(54) Title: STRUCTURE-BASED CONSTRUCTION OF HUMAN ANTIBODY LIBRARY

(57) Abstract: Methods and systems are provided for constructing recombinant antibody libraries based on three-dimensional structures of antibodies from various species including human. In one aspect, a library of antibodies with diverse sequences is efficiently constructed in silico to represent the structural repertoire of the verbrate antibodies. Such a functionally representative library provides a structurally diverse and yet functionally more relevant source of antibody candidates which can then be screened for high affinity binding to a wide variety of target molecules, including but not limited to biomacromolecules such as protein, peptide, and nucleic acids, and small molecules.

STRUCTURE-BASED CONSTRUCTION OF
HUMAN ANTIBODY LIBRARY

BACKGROUND OF THE INVENTION

5

Field of the Invention

The present invention relates generally to computer-aided design of human antibody sequence libraries, and, more particularly, relates to methods and systems for selecting and constructing fully human or

10   human-derived antibody library based on three-dimensional structural frameworks of vertebrate antibody repertoire.

Description of Related Art

Antibodies are made by vertebrates in response to various

15   internal and external stimuli (antigens). Synthesized exclusively by B cells, antibodies are produced in millions of forms, each with different amino acid sequence and a different binding site for antigen. Collectively called immunoglobulins (abbreviated as Ig), they are among the most abundant protein components in the blood, constituting about

20   20% of the total plama protein by weight.

A naturally occurring antibody molecule consists of two identical "light" (L) protein chains and two identically "heavy" (H) protein chains, all held together covalently by precisely located disulfide linkages. Chothia et al. (1985) J. Mol. Biol. 186:651-663; and Novotny and Haber

25   (1985) Proc. Natl. Acad. Sci. USA 82:4592-4596. The N-terminal regions of the L and H chains together form the antigen recognition site of each antibody.

The mammalian immune system has evolved unique genetic mechanisms that enable it to generate an almost unlimited number of

30   different light and heavy chains in a remarkably economical way by joining separate gene segments together before they are transcribed. For each type of Ig chain—κ light chains, λ light chains, and heavy chain—there is a sssseparate pool of gene segments from which a single peptide chain is eventually synthesized. Each pool is on a different

35   chromosome and usually contains a large number of gene segments

encoding the V region of an Ig chain and a smaller number of gene
segments encoding the C region. During B cell development a complete
coding sequence for each of the two Ig chains to be synthesized is
assembled by site-specific genetic recombination, bringing together the

5   entire coding sequences for a V region and the coding sequence for a C
region. In addition, the V region of a light chain is encoded by a DNA
sequence assembled from two gene segments— a V gene segment and
short joining or J gene segment. The V region of a heavy chain is
encoded by a DNA sequence assembled from three gene segments— a V

10   gene segment, a J gene segment and a diversity or D segment.

The large number of inherited V, J and D gene segments
available for encoding Ig chains makes a substantial contribution on its
own to antibody diversity, but the combinatorial joining of these
segments greatly increases this contribution. Further, imprecise joining

15   of gene segments and somatic mutations introduced during the V-D-J
segment joining at the pre-B cell stage greatly increases the diversity of
the V regions.

After immunization against an antigen, a mammal goes through
a process known as affinity maturation to produce antibodies with

20   higher affinity toward the antigen. Such antigen-driven somatic
hypermutation fine-tunes antibody responses to a given antigen,
presumably due to the accumulation of point mutations specifically in
both heavy-and light-chain V region coding sequences and a selected
expansion of high-affinity antibody-bearing B cell clones.

25   Structurally, various functions of an antibody are confined to
discrete protein domains (regions). The sites that recognize and bind
antigen consist of three complementarity-determining regions (CDRs)
that lie within the variable (V_H and V_L) regions at the N-terminal ends of
the two H and two L chains. The constant domains are not involved

30   directly in binding the antibody to an antigen, but are involved in
various effector functions, such as participation of the antibody in
antibody-dependent cellular cytotoxicity.

The domains of natural light and heavy chains have the same
general structures, and each domain comprises four framework regions,

35   whose sequences are somewhat conserved, connected by three hyper-

-2-

variable or CDRs. The four framework regions largely adopt a β-sheet conformation and the CDRs form loops connecting, and in some cases forming part of, the β-sheet structure. The CDRs in each chain are held in close proximity by the framework regions and, with the CDRs from

5 the other chain, contribute to the formation of the antigen binding site.

Generally all antibodies adopt a characteristic "immunoglobulin fold". Specifically, both the variable and constant domains of an antigen binding fragment (Fab, consisting of V_L and C_L of the light chain and V_H and $C_H 1$ of the heavy chain) consist of two twisted antiparallel β-

10 sheets which form a β-sandwich structure. The constant regions have three- and four-stranded β-sheets arranged in a Greek key-like motif, while variable regions have a further two short β strands producing a five-stranded β-sheet.

The V_L and V_H domains interact via the five-stranded β sheets to

15 form a nine-stranded β barrel of about 8.4 Å radius, with the strands at the domain interface inclined at approximately 50° to one another. The domain pairing brings the CDR loops into close proximity. The CDRs themselves form some 25% of the V_L/V_H domain interface.

The six CDRs, (CDR-L1, -L2 and –L3 for the light chain, and

20 CDR-H1, -H2 and –H3 for the heavy chain), are supported on the β barrel framework, forming the antigen binding site. While their sequence is hypervariable in comparison with the rest of the immunoglobulin structure, some of the loops show a relatively high degree of both sequence and structural conservation. In particular,

25 CDR-L2 and CDR-H1 are highly conserved in conformation.

Chothia and co-workers have shown that five of the six CDR loops (all except CDR-H3) adopt a discrete, limited number of main-chain conformations (termed canonical structures of the CDRs) by analysis of conserved key residues. Chothia and Lesk (1987) J. Mol.

30 Biol. 196:901-917; Chothia et al. (1989) Nature (London) 342:877; and Chothia et al. (1998) J. Mol. Biol. 278:457-479. The adopted structure depends on both the CDR length and the identity of certain key amino acid residues, both in the CDR and in the contacting framework, involved in its packing. The canonical conformations were determined

35 by specific packing, hydrogen bonding interactions, and stereochemical

constraints of only these key residues which serve as structural determinants.

Various methods have been developed for modeling the three dimensional structures of the antigen binding site of an antibody.

5   Other than x-ray crystallography, nuclear magnetic resonance (NMR) spectroscopy has been used in combination with computer modeling building to study the atomic details of antibody-ligand interactions. Dwek et al. (1975) Eur. J. Biochem. 53:25-39. Dwek and coworkers used spin-labeled hapten to deduce the combining site of the MoPC 315

10 myeloma protein for dinitrophenyl. Similar analysis has also been done anti-spin label monoclonal antibodies (Anglister et al. (1987) Biochem. 26: 6958-6064) and on the anti-2-phenyloxazolone Fv fragments (McManus and Riechmann (1991) Biochem. 30:5851-5857).

Computer-implemented analysis and modeling of antibody

15 combining site (or antigen binding site) is based on homology analysis comparing the target antibody sequence with those of antibodies with known structures or structural motifs in existing data bases (e.g. the Brookhaven Protein Data Bank). By using such homology modeling methods approximate three-dimensional structure of the target

20 antibody is constructed. Early antibody modeling was based on the conjecture that CDR loops with identical length and different sequence may adopt similar conformations. Kabat and Wu (1972) Proc. Natl. Acad. Sci. USA 69: 960-964. A typical segment match algorithm is as follows: given a loop sequence, the Protein Data Bank can be searched

25 for short, homologous backbone fragments (e.g. tripeptides) which are then assembled and computationally refined into a new combining site model.

More recently, the canonical loop concept has been incorporated into computer-implemented structural modeling of antibody combining

30 site. In its most general form, the canonical structure concept assumes that (1) sequence variation at other than canonical positions is irrelevant for loop conformation, (2) canonical loop conformations are essentially independent of loop-loop interactions, and (3) only a limited number of canonical motifs exist and these are well represented in the

35 database of currently known antibody crystal structures. Based on this

concept, Chothia predicted all six CDR loop conformations in the lysozyme-binding antibody D1.3 and five canonical loop conformations in four other antibodies. Chothia (1989), *supra.* It is also possible to improve modeling of CDRs of antibody structures by combining the

5   homology modeling with conformational search procedures. Martin, A.C.R. (1989) PNAS 86, 9268-72.

Besides modeling a specific antibody structure, efforts have been made in generating artificial (or synthetic) libraries of antibodies which are screened against one or more specific, target antigens. Various

10   artificial sequences are generated by site-specific or random mutagenesis on the antibody sequence, especially into the CDR regions of the variable domains. For example, Iba et al. used computer-driven model building system to change the specificity of antibodies against steroid antigens by introducing mutations into the CDR regions. Iba et

15   al. (1998) Protein Eng. 11:361-370. A phage-display library of Abs in which 16 residues of 17-α- hydroxyprogesterone (17-OHP) were mutated in three CDR regions of the heavy chain that appeared to form the steroid-binding pocket. The phage display library were screened against 17-OHP and cortisol that had been conjugated with bovine serum

20   albumin. Many clones were isolated that had retained 17-OHP-binding ability as well as clones with the newly developed ability to bind cortisol in addition to 17-OHP.

Phage display technology has been used extensively to generate large libraries of antibody fragments by exploiting the capability of

25   bacteriophage to express and display biologically functional protein molecule on its surface. Combinatorial libraries of antibodies have been generated in bacteriophage lambda expression systems which may be screened as bacteriophage plaques or as colonies of lysogens (Huse et al. (1989) Science 246: 1275; Caton and Koprowski (1990) Proc. Natl.

30   Acad. Sci. (U.S.A.) 87: 6450; Mullinax et al (1990) Proc. Natl. Acad. Sci. (U.S.A.) 87: 8095; Persson et al. (1991) Proc. Natl. Acad. Sci. (U.S.A.) 88: 2432). Various embodiments of bacteriophage antibody display libraries and lambda phage expression libraries have been described (Kang et al. (1991) Proc. Natl. Acad. Sci. (U.S.A.) 88: 4363; Clackson et

35   al. (1991) Nature 352: 624; McCafferty et al. (1990) Nature 348: 552;

Burton et al. (1991) Proc. Natl. Acad. Sci. (U.S.A.) 88: 10134; Hoogenboom et al. (1991) Nucleic Acids Res. 19: 4133; Chang et al. (1991) J. Immunol. 147: 3610; Breitling et al. (1991) Gene 104: 147; Marks et al. (1991) J. Mol. Biol. 222: 581; Barbas et al. (1992) Proc.

5   Natl. Acad. Sci. (U.S.A.) 89: 4457; Hawkins and Winter (1992) J. Immunol. 22: 867; Marks et al. (1992) Biotechnology 10: 779; Marks et al. (1992) J. Biol. Chem. 267: 16007; Lowman et al (1991) Biochemistry 30: 10832; Lerner et al. (1992) Science 258: 1313). Also see review by Rader, C. and Barbas, C. F. (1997) "Phage display of combinatorial

10   antibody libraries" Curr. Opin. Biotechnol. 8:503-508.

Generally, a phage library is created by inserting a library of a random oligonucleotide or a cDNA library encoding antibody fragment such as V_L and V_H into gene 3 of M13 or fd phage. Each inserted gene is expressed at the N-terminal of the gene 3 product, a minor coat protein

15   of the phage. As a result, peptide libraries that contain diverse peptides can be constructed. The phage library is then affinity screened against immobilized target molecule of interest, such as an antigen, and specifically bound phages are recovered and amplified by infection into *Escherichia coli* host cells. Typically, the target molecule of interest

20   such as a receptor (e.g., polypeptide, carbohydrate, glycoprotein, nucleic acid) is immobilized by covalent linkage to a chromatography resin to enrich for reactive phage by affinity chromatography) and/or labeled for screen plaques or colony lifts. This procedure is called biopanning. Finally, amplified phages can be sequenced for deduction of the specific

25   peptide sequences.

The sequences of the antibodies in these phage display libraries are from natural sources. For example, cDNA of antibody gene pools have been generated from immunized or naive human or rodents. Barbas and Burton (1996) Trends Biotech. 14:230-234 (immunized donors); De

30   Haard et al. (1999) J. Biol. Chem. 274:18218-18230 (naive B-cell Ig repertoires). The antibody cDNA library can be constructed by reverse transcription of RNA encoding the gene pool from total RNA samples isolated from B cells contained in peripheral blood supplied by human or animal. First strand cDNA synthesis is usually performed using the

35   method of Marks et al. in which a set of heavy and light chain cDNA

primers are designed to anneal to the constant regions for priming the systhesis of cDNA of heavy chain and light chains (both κ and λ) antibody genes in separate tubes. Marks et al. (1991) Eur. J. Immunol. 21:985-991.

5   Synthetic or artificial libraries of antibody sequences were constructed *in vitro* from human germline sequences. Griffiths et al. (1994) EMBO J. 13:3245-3260. Highly diverse repertoires of heavy and light chains were created entirely in vitro from a bank of human V gene segments and then, by recombination of the repertoire in bacteria, an

10   even larger (close to 6.5×10^{10}) synthetic library of Fab fragments were generated in bacteria and displayed on filamentous phage.

Highly diverse synthetic libraries of antibody sequences were also constructed based on consensus sequences of each germline family of human antibody repertoire. For example, a fully synthetic

15   combinatorial antibody library was constructed based on modular consensus frameworks and CDR3 regions in heavy and light chains randomized with trinucleotides. Knappik et al. (2000) J. Mol. Biol. 296:57-86. Knappik et al. analysed the human antibody repertoire in terms of structure, amino acid sequence diversity and germline usage.

20   Modular consensus framework sequences with seven V_H and seven V_L were derived to cover 95% of variable germline families and optimized for expression in E. coli. A consensus sequence was derived for each highly used germline family and optimized for expression in *E. coli.* Molecular modeling of their CDR loops of the consensus sequences

25   verified that all canonical classes were present. Diversity of the antibody library was created by replacing the CDR3 regions of seven V_H and seven V_L frameworks of the master genes by CDR3 library cassettte. A synthetic library of combinatorial antibody was generated from mixed trinucleotides and biased towards natural human antibody

30   CDR3 sequences. This library was cloned into phagemid and expressed as soluble proteins in the periplasm of E. coli.

SUMMARY OF THE INVENTION

The present invention provides a comprehensive methodology to map the functional space of proteins by exploiting the fundamental structure-sequence relationship within protein families. The methodology of the present invention provides for efficient *in silico* selection and construction of a library of antibodies with diverse sequences. By using the methodology libraries of antibodies can be constructed with diverse sequences in the CDR regions, and humanized frameworks of the variable regions having fully human, human-derived antibody, or antibody of human origin (collectively referred to herein as "human antibody") based on three-dimensional structures of antibodies generated by all species of vertebrates including human.

In one aspect of the invention, a method is provided for constructing a library of artificial antibodies *in silico* based on ensembles of 3D structures of existing antibodies of human origin, optional also including those of other vertebrate origins. By using the method, a master library of human antibody sequences can be selected to better represent all antibody structural repertoire in the vertebrate antibody repertoire that are functionally important for high affinity binding to antigens and eliciting antibody-dependent cellular responses.

Such a functionally representative library provides a structurally diverse and yet functionally more relevant source of antibody candidates which can then be screened for binding to a wide variety of target molecules, including but not limited to biomacromolecules such as protein, peptide, and nucleic acids, and small molecules.

In one embodiment, the method comprises the steps of:

clustering variable regions of a collection of antibodies having known 3D structures into at least two families of structural ensembles, each family of structural ensemble comprising at least two different antibody sequences but with substantially identical main chain conformations;

selecting a representative structural template from each family of structural ensemble;

profiling a tester polypeptide sequence onto the representative structural template within each family of structural ensemble; and

selecting the tester antibody sequence that is compatible to the structural constraints of the representative structural template.

5   According to the method, examples of the collection of antibodies include, but are not limited to, antibodies or immunoglobulins collected in a protein database such as the protein data bank of Brookhaven National Laboratory, genbank at the National Institute of Health, and Swiss-PROT protein sequence database.

10   The collection of antibodies having known 3D structures include any antibody having resolved X-ray crystal structure, NMR structure or a 3D structure based on structural modeling such as homology modeling.

The variable regions of a collection of antibodies may be the full
15   length of the heavy chain or light chain variable region or a specific portion of the heavy chain or light chain variable region, such as a CDR (e.g., V_H or V_L CDR1, CDR2, and CDR3), a framework region (FR, e.g., V_H or V_L FR1, FR2, FR3, and FR4), and a combination thereof.

Also according to the method, the clustering step includes
20   clustering the collection of antibodies such that the root mean square difference of the main chain conformations of antibody sequences in each family of the structural ensemble is preferably less than 4 Å, more preferably less than 3 Å, and most preferably less than 2 Å.

Optionally, the clustering step includes clustering the collection
25   of antibodies such that the Z-score of the main chain conformations of antibody sequences in each family of the structural ensemble is preferably more than 2, more preferably more than 3, and most preferably more than 4.

The clustering step may be implemented by an algorithm
30   selected from the group consisting of CE, Monte Carlo and 3D clustering algorithms.

Also according to the method, the profiling step includes reverse threading the tester polypeptide sequence onto the representative structural template within each family of structural ensemble.

Optionally, the profiling step is implemented by a multiple sequence alignment algorithm such as the profile HMM algorithm and PSI-BLAST (Position-Specific Iterated BLAST).

5   When the representative structural template is adopted by a CDR region, the profiling step includes profiling the tester polypeptide sequence that is a human or non-human antibody onto the representative structural template within each family of structural ensemble.

When the representative structural template is adopted by a FR
10   region, the profiling step includes profiling the tester polypeptide sequence that is a human or non-human antibody, preferably a human germline antibody sequence, onto the representative structural template within each family of structural ensemble.

In another aspect of the invention, a method is provided for in
15   silico selection of antibody sequences based on structural alignment with a target structural template. Diverse sequences which still retain the same functionally relevant structure as the target structural template can be selected by using reverse threading, the profile HMM algorithm and PSI-BLAST. By using the method, a library of diverse
20   antibody sequences can be constructed and screened experimentally in vitro or in vivo for antibody mutants with improved or desired function(s).

In one embodiment, the method comprises the steps of:

providing a target structural template of a variable region of one
25   or more antibodies;

profiling a tester polypeptide sequence onto the target structural template; and

selecting the tester polypeptide sequence that is structurally compatible with the target structural template.

30   According to the method, the target structural template may be a 3D structure of a heavy chain or light chain variable region of an antibody (e.g., CDR, FR and a combination thereof), or a structural ensemble of heavy chain or light chain variable regions of at least two different antibodies.

Also according to the method, the profiling step includes reverse threading the tester polypeptide sequence onto the target structural template.

Optionally, the profiling step is implemented by a multiple
5   sequence alignment algorithm such as the profile HMM algorithm and PSI-BLAST.

Also optionally, when the target structural template is adopted by a CDR region of the target antibody, the profiling step includes profiling a heavy chain or light chain variable region of the tester
10 polypeptide sequence that is either a human antibody or a non-human antibody.

Also optionally, when the target structural template is adopted by a FR region of the target antibody, the profiling step includes profiling a heavy chain or light chain variable region of the tester
15 polypeptide sequence that is a human antibody, preferably a human germline antibody, onto the target structural template.

According to any of the above method, the tester polypeptide sequence may be the sequence or a segment sequence of an expressed protein, preferably an antibody, more preferably a human antibody, and
20 most preferably a human germline antibody sequence.

According to any of the above method, the selecting step includes selecting the tester polypeptide sequence by using an energy scoring function selected from the group consisting of electrostatic interactions, van der Waals interactions, electrostatic solvation energy, solvent-
25 accessible surface solvation energy, and conformational entropy.

Optionally, the selecting step includes selecting the tester polypeptide sequence by using a scoring function incorporating a forcefield selected from the group consisting of the Amber forcefield, Charmm forcefield, the Discover cvff forcefields, the ECEPP forcefields,
30 the GROMOS forcefields, the OPLS forcefields, the MMFF94 forcefield, the Tripose forcefield, the MM3 forcefield, the Dreiding forcefield, and UNRES forcefield, and other knowledge-based statistical forcefield (mean field) and structure-based thermodynamic potential functions.

In yet another aspect of the invention, a method is provided for in
35 silico selection of antibody sequences based on homology alignment

with a target sequence template. Remote homologues with diverse
sequences but retaining the same functionally relevant structure can be
selected by using profile hidden Markov Model (HMM) and PSI-BLAST.
By using the method, a library of diverse antibody sequences can be
5   constructed with a relatively smaller size than that constructed by
complete randomization of the target sequence. This library can then be
filtered using certain cutoff value based on, for example, the occurrence
frequency of variants in each amino acid residue position, and screened
experimentally in vitro or in vivo for antibody mutants with improved or
10 desired function(s).

In one embodiment, the method comprises the steps of:

providing a target sequence of a heavy chain or light chain
variable region of an antibody;

aligning the target sequence with a tester polypeptide sequence;
15 and

selecting the tester polypeptide sequence that has at least 15%
sequence homology with the target sequence.

According to the method, the target sequence may be the full
length of the heavy chain or light chain variable region, or a specific
20 portion of the variable region, such as a CDR, a framework (FR) region
and a combination thereof.

Also according to the method, the aligning step includes aligning
the target sequence with the polypeptide segment of the tester protein
by using a sequence alignment algorithm selected from the group
25 consisting of BLAST, PSI-BLAST, profile HMM, and COBLATH.

Also according to the method, when the target sequence is a CDR
region of the target antibody, the alignment step includes aligning any
protein sequences that is of either human or non-human origin with the
target sequence.

30 Also according to the method, when the target sequence is a CDR
region of the target antibody, the tester polypeptide sequence is a heavy
chain or light chain variable region of a human or non-human antibody.

Also according to the method, when the target sequence is a FR
region of the target antibody, the tester polypeptide sequence is a heavy

chain or light chain variable region of a human antibody, preferably a
human germline antibody sequence.

Also according to the method, the selecting step includes
selecting the polypeptide segment of the tester protein that has
5   preferably at least 25%, preferably at least 35%, and most preferably at
least 45% sequence homology with the target sequence.

According to any of the above methods, the method further
comprises:

introducing the DNA segment encoding the selected tester
10   polypeptide into cells of a host organism;

expressing the DNA segment in the host cells such that a
recombinant antibody containing the selected polypeptide or antibody
sequence is produced in the cells of the host organism; and

selecting the recombinant antibody that binds to a target antigen
15   with affinity higher than 10^6 M^{-1}.

The recombinant antibody may be a fully assembled antibody, a
Fab fragment, an Fv fragment, or a single chain antibody.

The host organism includes any organism or its cell line that is
capable of expressing transferred foreign genetic sequence, including
20   but not limited to bacteria, yeast, plant, insect, and mammals.

The target antigen to be screened against includes small
molecules and macromolecules such as proteins, peptides, nucleic
acids and polycarbohydates.

25   **BRIEF DESCRIPTION OF FIGURES**

Figure 1 illustrates a flow chart of a computer-implemented process
that can be used in the present invention to construct an antibody
library in silico.

30

Figure 2 shows 7 V_H and 7 V_L consensus sequences for 7 V_H and 7 V_L
framework of Hucal library in fasta format by Knappik et al., supra.

Figure 3 shows the structures of the seven V_H sequences superimposed
35   on each other. The structures are aligned by superimposing the Ca

atoms using the CE with RMSD < 2Å and Z-score > 4.

Figure 4 shows **(A)** the Ca trace of the superimposed structures of these 3 V$_H$ sequences (1DHA in green, 1DHO in cyan, and 1DHW in yellow); **(B)** the superimposed structures with a ribbon representation of the β-sheets of the VH frameworks. As shown in both **Figures 4A and 4B**, the 3 V$_H$ sequences (1DHA, 1DHO, and 1DHW) collapse into one structural family with RMSD <0.7 Å and Z-score >6 using 1DHA as standard, even though their sequence identity ranges widely from 72% to 87% relative to 1DHA.

Figure 5 shows the structures of the seven V$_L$ sequences retrieved from the PDB and superimposed on each other. The structures are aligned by using 1DGX as the reference structure with RMSD< 1.6Å and Z-score >6. The seven V$_L$ sequences have a wide range of conformational variability, especially in the CDR regions highlighted (The structural flexibility at N- and C-termini are discarded here).

Figure 6 shows the superpositioned 1DGX(green), 1DH4 (yellow), 1DH5 (color cyan) and 1DH6 (magenta) with similar conformation but varying length in the CDR regions. By using the CE algorithm, four V$_L$ sequences (1DGX, 1DH4, 1DH5 and 1DH6) of the 7 consensus sequences families can be clustered into one structural family with RMSD < 0.6 Å and Z-score >6 and with sequence identity ranging from 67% to 80% using 1DGX as the structure reference. These four sequences also belong to the V$_L$ kappa sequence family.

Figure 7 shows three superimposed structures of 1DH7, 1DH8, and 1DH9 in lamda variable light chain, can be clustered into 1 structure family with RMSD < 1.5Å and Z-score > 6 using 1DGX as the reference.

Figure 8 shows in **(A)** that CDR1 regions of the three lamda (λ) V$_L$ sequences (1DH7, 1DH8 and 1DH9) adopt similar conformations with RMSD < 1Å. **(B)** that CDR1 regions of the 4 kappa (κ) VL sequences (1DH4, 1DH6, 1DGX and 1DH5) adopt similar conformations with

RMSD < 0.6Å and gaps of 1-6 amino acids. **(C)** that CDR1 regions of the two kappa (κ) V_L sequences (1DH4 and 1DH6) adopt similar conformations with RMSD < 0.6Å and 1 amino acid gap in CDR1. Thus, structures of these two kappa V_L sequences are further clustered

5   into one structural family according to the present invention. **(D) that** CDR1 regions of the two kappa (κ) V_L sequences (1DGX and 1DH5) adopt similar conformations with RMSD < 0.6Å and 1 amino acid gap in CDR1.

10   **Figure 9** shows that clustering of the structures adopted by the seven consensus germline V_L sequences based on the structural families in the CDR1 region led to two to three distinct families of antibody structures: (1DH7, 1DH8 and 1DH9) for lamda variable light chains, (1DH4 and 1DH6), and/or (1DGX and 1DH5) for kappa variable light

15   chains. The members within each family adopt similar conformations in their CDR1 regions with varying length in amino acids.

      Figure 10 shows the PDB IDs of the consensus sequences of V_H and V_L, residues aligned, high score, P(N) sum, smallest probability, % identity

20   with the query sequence, the germline family to which the identified germline sequence belongs.

      Figure 11 shows the homology alignment for each of the selected human antibody germline sequences with the query sequence.

Figure 13 shows the top sequences from germline gene segments
selected using the profile HMM method for various re-clustered
structures.

5   **DEFINITION**

Structural family: a group of structures that are clustered into a family
based on some empirically chosen cutoff values of the root mean square
deviation (RMSD) (for example, their Ca atoms of the aligned residues)

10   and statistical significance (Z-score). These values are empirically
decided after an overall comparison among structures of interest. For
example, for CE algorithms, the starting criteria used are RMSD $<$ 2 Å
and Z-score > 4.

15   Structural ensemble: It is well known that in the structural
determination by NMR (nuclear magnetic resonance), the ensemble of
structures rather than a single structure, with perhaps several
members, all of which fit the NMR data and retain good
stereochemistry, is deposited with the Protein Data Bank (PDB).

20   Comparison between the models in this ensemble provides some
information on how well the protein conformation was determined by
the NMR constraints. In structural clustering, it is important to analyze
the all members within a structural cluster to understand some
consensus information about the distribution of all structural templates

25   within a family and constraints on their sequences or sequence profiles
within a structural family. It should be pointed out that all the
sequences corresponding to NMR-determined ensemble structures have
the same sequences (one protein with variable conformations). The
structural ensemble here in the present invention refers to different

30   proteins with variations in sequence and/or length but have similar
main chain conformations.

Ensemble average or representative structure: if all members within a
structural cluster has the same length of amino acids, the positions of

35   atoms in main chain atoms of all structures are averaged, and the

average model is then adjusted to obey normal bond distances and angles ("restrained minimization"), similar to NMR-determined average structure. If all members within a structural cluster vary in the length of amino acids, a member which is representative of the average characteristics of all other members within the cluster will be chosen as the representative structure.

Canonical structures: the commonly occurring main-chain conformations of the hypervariable regions.

Structural repertoire: the collection of all structures populated by a class of proteins such as the modular structures and canonical structures observed for antibody framework and CDR regions.

Sequence repertoire: collection of sequences for a protein family.

Functional repertoire: a collection of all functions performed by proteins, such as the antibodies' diverse functional epitopes that are capable of binding to various antigens.

Germline gene segments: refers to the genes from the germline (the haploid gametes and those diploid cells from which they are formed). The germline DNA contain multiple gene segments that encode a single immunoglubin heavy or light chain. These gene segments are carried in the germ cells but cannot be transcribed and translated into heavy and light chains until they are arranged into functional genes. During B-cell differentiation in the bone marrow, these gene segments are randomly shuffled by a dynamic genetic system capable of generating more than 10^8 specificities. Most of these gene segments are published and collected by the germline database.

Rearranged immunoglobulin sequences: the functional immunoglobulin gene sequences in heavy and light chains that are generated by transcribing and translating the germline gene segments during B-cell differentiation and maturation process. Most of the

rearranged immunoglobulin sequences used here are from Kabat-Wu database.

BLAST: Basic Local Alignment Search Tool for pairwise sequence
5   analysis. BLAST uses a heuristic algorithm with position-independent scoring parameters to detect similarity between two sequences.

PSI-BLAST: The Position-Specific Iterated BLAST, or PSI-BLAST program performs an iterative search in which sequences found in one
10   round of searching are used to build a score model for the next round of searching. In PSI-BLAST the algorithm is not tied to a specific score matrix. Traditionally, it has been implemented using an AxA substitution matrix where A is the alphabet size. PSI-BLAST instead uses a QxA matrix, where Q is the length of the query sequence; at each
15   position the cost of a letter depends on the position with respect to the query and the letter in the subject sequence. Two PSI-BLAST parameters have been adjusted: the pseudocount constant default has been changed from 10 to 7, and the E-value threshold for including matches in the PSI-BLAST model has been changed from 0.001 to
20   0.002.

COBLATH: A method that combines PSI-BLAST with Threading method for fold recognition and query-template alignment. It might be used to compare the compatibility between sequences and structural templates.
25

Profile Hidden Markov Model (profile HMMs): statistical models of the primary structure consensus of a sequence family. They use position-specific scores for amino acids and for opening and extending an insertion and deletion to detect remote sequence homologues based on
30   the statistical description of the consensus of a multiple sequence alignment. The multiple sequence alignments are given either by the multiple sequence alignment program such as ClustalW or structure-based multiple sequence alignment given by structural clustering.

35   Threading: a process of assigning the folding of the protein by

threading its sequence to a library of potential structural templates by
using a scoring function that incorporates the sequence as well as the
local parameters such as secondary structure and solvent exposure.
The threading process starts from prediction of the secondary structure

5   of the amino acid sequence and solvent accessibility for each residue of
the query sequence. The resulting one-dimensional (1D) profile of the
predicted structure is threaded into each member of a library of known
3D structures. The optimal threading for each sequence-structure pair
is obtained using dynamic programming. The overall best sequence-

10   structure pair constitutes the predicted 3D structure for the query
sequence.

Reverse Threading: a process of searching for the optimal sequence(s)
from sequence database by threading them onto a given target

15   structure and/or structure cluster. Various scoring functions may be
used to select for the optimal sequence(s) from the library comprising
protein sequences with various lengths.

Reverse Engineering: the procedure to select and construct sequence or

20   sequence libraries that are compatible to the structural constraints is
called reverse engineering including but not limited to reverse
threading.

Supervariable Region of Antibody: regions within antibody CDRs that

25   show diverse structure, sequence and chain length variability compared
to the other regions of CDRs or CDR ensembles which are relatively
constant in structure, sequence and chain length. As exemplified in
Figure 12C, the super-variability of a region of a specific CDR family
can be exploited in CDR library construction.

30
DETAILED DESCRIPTION OF THE INVENTION

The present invention provides a system and method for efficient
in silico selection and construction of fully human and human-derived

35   antibody libraries. The process is carried out computationally (i.e., *in*

silico) in a high throughput manner by mining the ever-expanding
databases of protein sequences of all organisms, especially human. The
inventive methodology is developed by combining database mining of
evolutionary sequences from nature with computational design of
5   structurally relevant variants of the nature sequences.

In one aspect of the invention, the methodology is implemented
by a computer system which computationally selects those human
antibody sequences based on three-dimensional structural ensemble
and/or ensemble average represented by a limited, discrete number of
10   classes (or clusters) of antibody structures. By using the method, a
master library of human antibody sequences can be constructed to
better represent all antibody structures in the vertebrate antibody
repertoire that are functionally important for high affinity binding to a
large variety of antigens and eliciting antibody-dependent cellular
15   responses.

In another aspect of the invention, the methodology is
implemented by a computer system which computationally selects from
the protein databases protein sequences, particularly antibody
sequences, based on structural alignment with a target structural
20   template. Diverse sequences which still retain the same functionally
relevant structure as the target structural template can be selected by
using reverse threading. By using the method, a library of diverse
antibody sequences can be constructed and screened experimentally in
vitro or in vivo for antibody mutants with improved or desired
25   function(s).

In yet another aspect of the invention, the methodology is
implemented by a computer system which computationally selects from
the protein databases protein sequences, particularly antibody
sequences, based on homology alignment with a target sequence
30   template. Remote homologues with diverse sequences but retaining the
same functionally relevant structure can be selected by using structure-
based sequence alignment methods such as profile hidden Markov
Model (HMM). By using the method, a library of diverse antibody
sequences can be constructed with a relatively smaller size than that
35   constructed by complete randomization of the target sequence. This

library can then be thoroughly screened experimentally in vitro or in vivo for antibody mutants with improved or desired function(s).

The inventive methodology can be used to design any protein with novel function or improved function over the target protein which serves as a lead in the process. In particular, mutant antibodies can be designed to include diverse sequences in the CDR regions, and to replace non-human sequences in the frameworks of the variable regions with human ones to reduce immunogenicity of the designed antibody when used as human therapeutics.

The library constructed by using the inventive methodology provides a structurally diverse and yet functionally more relevant source of antibody candidates for further screening for novel antibody with high affinity against a wide range of antigens and having no or minimum immunogenicity to human subject treated with antibody therapeutics.

1.   Principles of *in silico* selection and construction of a master library of functionally representative human antibody

Antibody is a unique class of proteins which play profound roles in a vertebrate's ability to defend itself against infection by neutralizing (or inactivating) viruses and bacterial toxins, and by recruiting the complement system and various types of white blood cells to kill extracellular microorganisms and larger parasites.

Like every protein of some biological significance, the biological functions of the proteins depend directly on the three-dimensional (3D) structure of the protein. The 3D structure or conformation determines the activity of an enzyme, how a receptor interacts with its ligand, and the affinity of the binding between the receptor and ligand. Thus, it would be biologically more relevant to screen a library of protein such as antibody based on the 3D structure a particular protein sequence adopts rather than the primary DNA or amino acid sequence of the protein.

In particular, as two of the most important handlers to map the functional space of proteins, the sequence and structure information of

antibodies have been accumulated for more than a few decades. Extensive analysis on their patterns have provided some of the most detailed understanding of fundamental process for molecular recognitions, which has a direct impact on the combinatorial technology

5   in chemistry and biology.

So far, major efforts in mapping the functional diversity of antibodies have been focused on capturing the complexity in antibody sequence space by either simply increasing the size of antibody sequence pool (the so-called one-pot approach) or by generating large

10   synthetic libraries in CDR regions. Only recently has systematic analysis of antibody sequence repertoire been utilized to design highly diverse consensus sequence library based on highly used human, germline sequences as observed in the rearranged human antibody sequences. Knappik et al., *supra*. These consensus sequences were

15   further analyzed to account for the canonical structures for the CDR regions.

In the present invention a distinctly novel approach is utilized to map the functional repertoire of antibody molecules. This approach is taken by exploiting the characteristics of antibody in sequence diversity

20   and global structural conservation.

It is recognized that although a protein may have astronomical number of possible conformations (about 1016 for a small protein of 100 residues (Dill (1985) Biochem. 24:1501-1509), all antibodies adopt a characteristic "immunoglobulin fold" globally. The natural antibody

25   repertoire shows an amazing ability in recognizing a wide variety of molecules. To confer such diverse functions of binding ability to a vertebrate's antibodies, an extremely diverse sequence repertoire (about 10^{12} possible combinations between the sequences of mouse heavy chain and light chains) is created by random genomic splicing of heavy

30   and light chains with high variability in both sequence and length in their CDRs.

The structural repertoire to accommodate the much larger sequence repertoire is, however, surprisingly small. Only a limited number of canonical backbone conformations are found to account for

35   structures adopted by the CDRs that are docked onto highly conserved

immunoglobin scaffold.

1)   General approach

     The general approach for constructing a structure-based human

5   library is illustrated by a flow chart in **Figure 1**.

     As illustrated in **Figure 1**, antibody structures and models in

various protein structure databases such as the PDB are collected. The

structural repertoire of these antibody molecules are mapped out in

their three dimensional shape space. It is believed that conservation

10   and variation in the shape space should make it possible to develop

some general frameworks that remain constant across different species.

On the other hand, variation in the shape space should make it

possible to capture the functional diversity of antibody against a wide

array of antigens in specific antibody regions.

15   Referring to **Figure 1**, the variable regions in shape space are

clustered either separately (such as CDR3) or in combination (CDR1 &

CDR2) into distinct families with or without certain conserved

structural frameworks.

     Still referring to **Figure 1**, these structural clusters, the

20   ensemble average, and/or their corresponding sequence profiles are

used to map out the corresponding sequence in human germline (or in

a rearranged antibody sequence database) to find optimal sequences or

sequence profiles within each family.

     As diagramed in three boxes in the middle portion of **Figure 1**, at

25   least three approaches can be taken to exploit the information

generated by structure-based clustering of target antibody sequence(s).

As described in the left box, one approach is to directly select

sequences that fit onto the target structural template by using

algorithms such as reverse threading, PSI-BLAST and profile HMM. For

30   example, a library of recombinant antibodies can be generated by 1)

selecting from a human antibody germline database sequence segments

that fit onto a structural template of a target FR region of an antibody;

2) selecting from a protein database sequence segments that fit onto a

structural template of a target CDR region of the antibody; and 3)

35   combining the selected FR and CDR segments to build the library of

recombinant antibodies which are then synthesized and screened against a target antigen in vitro or in vivo.

As described in the right box in the middle section of **Figure 1**, another approach is to indirectly select antibody sequences using a target sequence or sequence profile built based on a structural template of a target antibody. For example, a library of recombinant antibodies can be generated by 1) aligning the target sequence or sequence profile with tester sequences from a protein database (e.g., human germline antibody sequence database or PDB) by using BLAST or multiple sequence alignment methods such as profile HMM; 2) selecting the tester sequences with homology to the target sequence (e.g., sequence homology of at least 15%); and optionally 3) evaluating the structural compatibility of the selected tester sequence with the structure template of the target sequence or sequence profile. This process can be carried out to construct a library of recombinant antibodies by targeting a particular region of an antibody such as a CDR, FR, and combination thereof. The selected tester sequences may be profiled based on variability in each amino acid residue and those variants with low occurrence frequency (e.g., 5 times out of 100 selected tester sequences) may be filtered and discarded. The rest of the selected tester sequences may be pooled and combined by a combinatorial combination of the amino acid variants in each residue position. The tester sequences selected by targeting the CDR region and the ones targeting the FR regions may also be combined; and the combined sequences may be filtered based on their structural compatibility with the target antibody. The library of recombinant antibodies can be synthesized and screened against a target antigen in vitro or in vivo.

As described in the middle box in the middle section of **Figure 1**, yet another approach is to select antibody sequences based on a target structural template combining methods described in the left and right boxes. For example, a library of recombinant antibodies can be generated by 1) aligning the sequence or sequence profile of the target structural template with tester sequences from a protein database (e.g., human germline antibody sequence database or PDB) and reverse threading the tester sequences onto the target structural template by

using a structure/sequence dual selection algorithm such as
COBLATH; and 2) selecting the tester sequences with homology to the
target sequence (e.g., sequence homology of at least 15%) and
structurally compatible with the target structural template. This
5   process can be carried out to construct a library of recombinant
antibodies by targeting a particular region of an antibody such as a
CDR, FR, and combination thereof. The selected tester sequences may
be profiled based on variability in each amino acid residue and those
variants with low occurrence frequency (e.g., 5 times out of 100 selected
10   tester sequences) may be filtered and discarded. The rest of the
selected tester sequences may be pooled and combined by a
combinatorial combination of the amino acid variants in each residue
position. The tester sequences selected by targeting the CDR region
and the ones targeting the FR regions may also be combined; and the
15   combined sequences may be filtered based on their structural
compatibility with the target antibody. The library of recombinant
antibodies can be synthesized and screened against a target antigen in
vitro or in vivo.

There are several advantages associated with this approach of
20   mapping the functional space of proteins using diversity libraries that
are designed by sampling the diversity in shape space rather than in
sequence space.

First, protein-protein interactions between ligand and receptor,
antigen and antibody are conducted in well–defined conformation in
25   space. Therefore, antibody libraries should be designed to map the 3-
dimensional space populated by antibodies in order to target antigens
with different shapes.

Second, compared to the larger sequence repertoire, structure
repertoire of antibodies is limited to a small number of canonical
30   structures in its main chain conformations in the CDR regions which
are docked onto a common core structure for both the variable light and
heavy chains. The simplicity in structure repertoire makes it easy to
map the functional diversity based on variation in its 3-dimensional
space and simple to cluster seemly complicated sequence pools into
35   distinct families for library construction.

Third, it is conceived that the conserved nature of the structural repertoire of immunoglobins across very different species (Barre et al. (1994) "Structural conservation of hypervariable regions in immunoglobins evolution" Nature Struct. Biol. 1:915-920) that clustering structure repertoire of antibodies from different species into distinct families is a viable approach to map its functional space. This approach is simple yet functionally more relevant for selecting and constructing the diversity libraries once it is applied to the sequence repertoire for a specific species. This is particularly important for constructing human antibody libraries for therapeutic application or for humanizing murine antibodies by using human-derived sequence repertoire for its counterparts. In contrast, sequence homology-based approaches would be less flexible and hard to transfer from species to species if sequence homology is relatively low.

Moreover, the structure-based construction of sequence libraries makes it possible to apply various methods developed in structural biology to filter apparent complexity in sequence spaces based on structural or physical principles, in addition to the tools used in sequence analysis that are largely relied on the principles of evolution.

Accordingly, the present invention provides a method of constructing a master library of functionally representative antibody. This master library is formed by a repertoire of antibody sequences adopting distinct classes of structures that covers, ideally, almost all of the 3D structural ensembles and/or ensemble averages of all vertebrate antibodies.

According to the present invention, a master library of functionally representative antibody is represented by a library of antibody sequences adopting distinct classes of structures that covers, ideally, almost all families of the 3D structures of all vertebrate antibodies. Although a protein may have astronomical number of possible sequence combinations (about 10^{16} for a small protein of 100 residues (Dill (1985) Biochem. 24:1501-1509), all antibodies adopt a characteristic "immunoglobulin fold" globally. The natural antibody repertoire shows an amazing ability in recognizing a wide variety of molecules. To confer such diverse functions of binding ability to a

vertebrate's antibodies, an extremely diverse sequence repertoire (about 10^{12} possible combinations between the sequences of mouse heavy chain and light chains) is created by random genomic splicing of heavy and light chains with high variability in both sequence and length in

5   their CDRs.

The structural repertoire to accommodate the much larger sequence repertoire is, however, surprisingly small. Only a limited number of canonical backbone conformations are found to account for structures adopted by the CDRs that are docked onto highly conserved

10   immunoglobulin scaffold.

According to the present invention, it is believed that antibody achieves its functional diversity by decorating a diverse array of amino acids onto a finite number of CDR canonical structures. The present invention clusters antibodies with experimental or modeled structures

15   into distinct families. By clustering the antibodies according to their 3D structures instead of using conventional methods of classification based on sequence homology, each family of the structure repertoire should better represent the population of antibodies with binding geometry complementary to the recognition sites of potential antigens, although

20   the binding affinity could be further optimized by matching the shape and chemical nature of the specific amino acids. Therefore, the approach taken in the present invention tends to maximize the functional diversity of antibody in recognizing and binding to a wide array of antigens *in silico* and meanwhile to minimize the sequence

25   space required for efficient screening *in vitro* or *in vivo*.

2)   Construction of antibody sequence library based on structural constraints

30   Once structural families are identified, either the cluster containing multiple members, a representative member, or an ensemble average of the cluster if possible, can be used as structural constraints to either select for optimal sequences or to construct sequences for further constructing sequence libraries.

35   There are several ways to use these structural families from

sampling antibody structure databases as the constraints for constructing desired sequence libraries. The main chain conformations of 3D structures within a structural family or cluster are called structure ensembles or structure templates. The ensemble average is

5　　referred to the average structure of all members within a structure cluster or family when it is physically meaningful to take average of the main chain conformations. If it is not physically meaningful or possible to take average for all members within a structural cluster or family due to the difference in length, etc. a representative structure may be used

10　　to represent the "average structural properties" of all members within a structural family or cluster. The structure ensembles or templates, ensemble average, or representative structures described above are collectively referred to herein as the "structural templates".

The difference in using these terms in describing structural

15　　constraints depends on how much structural constraint within a cluster should be included in constructing sequence libraries. For structural constraints, the most stringent and reasonable approach should be to include all ensemble structures or templates within a cluster or family. The ensemble average if done properly, may be the

20　　simplest structural constraint and easy to compute. If taking ensemble average is not physically meaningful, the representative structure may be a compromise to replace constraints by structure cluster.

Once the structural constraints are identified, there are several ways to construct sequence libraries by applying structural constraints.

25　　The procedure to select and construct sequence or sequence libraries that are compatible to the structural constraints is called reverse engineering including but not limited to reverse threading. However, an important aspect of current invention is to restrict the sequence database for library construction to specific species and/or to even the

30　　specific population of the same species. For therapeutic purpose, the human immunoglobulin sequence database are preferably used to construct human-derived antibody libraries, especially in the frameworks of the variable regions. In the CDR regions, sequences with non-human origins may optionally be used to increase the diversity of

35　　these regions so as to increase the chance of finding antibodies with

novel or improved function(s). The methods in applying both the physical and evolutionary constraints to construct sequence libraries are described in detail below.

One method is to use the sequence that is compatible to the

5   ensemble average structure or the representative member within a structure cluster to search for the optimal sequences from the germline sequence database. This will usually yield the sequence with the highest sequence identity to the query sequence using BLAST as demonstrated in Section 3 below (**Figures 10** and **11**).

10   The clustered structures within a structure family can give multiple sequence alignments based on 3D structures. These aligned sequences might come from different species; they may be close or remote sequence homologues. The multiple sequence alignment can be used, however, to build a profile Hidden Markov Model (HMM); and this

15   HMM will then be used to search for the close and/or remote human homologues from human sequence database such as the human germline and/or rearranged sequence database as demonstrated in Section 3 below (**Figures 12** and **13A-C**).

A more direct way to search for sequences compatible to

20   structural constraints is to thread amino acid sequences from human germline and/or rearranged sequence database onto structure templates of the structural cluster and to find out the optimal scoring sequences on their target structure templates. These sequences can be then used for constructing sequence libraries for the structure

25   cluster. This procedure is called reverse threading because it tries to find the best sequences fitting to the target structure templates, which is the opposite of threading which tries to find the best structure template from a structure library for a given sequence.

Additionally, the top hits of the sequences found for a structure

30   cluster or queried sequences may be profiled by threading multiple amino acids at each position in a combinatorial approach to select for the best "consensus sequence" compatible with the structural ensemble and/or ensemble average. This process of searching for consensus sequence is different from the consensus sequence from the method of

35   using simple sequence average at each position described in Knappik,

et al, *supra*. The consensus sequence according to the present invention is created using the physically oriented reverse engineering approach using all possible combination of amino acids that are allowed at each position from the retrieved sequences but are optimized by
5   scoring their compatibility with the structural constraints.

The human antibody sequences that are selected according to these criteria for the framework regions can serve as the sequence template for building a master framework for constructing the human antibody library of the present invention. These selected human
10   sequences are then pooled together and included in the master framework. The same methods can be used to construct the sequence libraries for CDR regions if the structure templates for each canonical structure family of CDRs are used to construct the sequence libraries for these regions.

15   Once the master framework of human antibody is constructed, mutagenesis can be carried out to diversify specified region(s) in the master framework. For example, CDR regions, especially CDR3 of the heavy chain, of the master framework can be randomly mutagenized to mimic the natural process of antibody diversification. The mutagenized
20   antibody sequence may be further selected *in silico* based their compatibility to the structural ensemble average. All of the antibody sequences selected in these processes are pooled to form a master library of human antibody which can be screened against a wide range of antigens *in vitro* or *in vivo*.

25   Since the selection and construction of the antibody library of the present invention is based on structural clustering, not simple sequence homology alignment, it is thus possible to further limit the number of antibody sequences in the library and yet not to sacrifice the functionally relevant sequences. For example, multiple human
30   antibody sequences may be highly diverse in their sequences and yet adopt the same 3D structure when threaded onto the structural ensemble average.

Further, for those antibody sequences mutagenized randomly in the CDR3 region, not all structures of randomized CDR3 are compatible
35   with the framework structural ensemble averages. Consequently, a

fewer number of CDR3 loops that are structurally diverse will be
selected, and therefore a fewer number of human sequences selected.
As a result, the sequence space of antibody to be screened is reduced in
size without sacrificing diversity in antibody functionality.

5   By using the method, a master library of human antibody
sequences is selected and constructed to better represent all antibody
structures in the vertebrate antibody repertoire that are functionally
important for high affinity binding to antigen and eliciting antibody-
dependent cellular responses.   Such a functionally representative
10   library provides a structurally diverse, and yet functionally more
relevant source of antibody candidates which can then be screened for
binding to a wide variety of target molecules, including but not limited
to biomacromolecules such as protein, peptide, and nucleic acids, and
small molecules.

15   The method of present invention is an efficient way of
constructing a digital library of antibody which represents most of the
3D structures of antibodies that are functionally relevant. Thus, the
human antibody sequences selected from the reverse engineering
process such as threading are finite and yet covers most of the
20   functionally relevant structures of antibody in human antibody gene
pool.

          In contrast, the current methods of construction of antibody
library in vitro involve isolation of cDNA libraries from immunized
human antibody gene pool, naive B-cell Ig repertoire, or particular
25   germline sequences. Barbas and Burton (1996), supra; De Haard et al.
(1999), supra; and Griffiths et al (1994), supra. These libraries are very
large and extremely diverse in terms of antibody sequences.

          The conventional approach is to create a library of antibody as
large, and as diverse as possible to mimic immunological response to
30   antigen in vivo. Typically, these large libraries of antibody are displayed
on phage surface and screened for antibodies with high affinity binding
ability to a target molecule. Such a "fishing in a large pond" or "finding
a needle in a huge hey stack" approach is based on the assumption that
simple increase in the size of sequence repertoire should make it more
35   likely to fish out the antibody that can bind to a target antigen with

high affinity.

There may be several problems associated with such a conventional approach. A simple increase in the size of sequence library may not necessarily correlate with an effective increase in

5　　　functional diversity. Further, due to the physical limit on making an extremely large experimental library, it may be very difficult to construct a library with diversity over 10^{11} in vitro in the lab. The library that is actually screened experimentally probably presents only a fraction of the sequence repertoire at the theoretically predicted size. In

10　　addition, there is legitimate concern that with the difficulties and the under representation problems associated with handling and manipulation of an extremely large library in vitro, time and money may be lost in an effort trying to increase the size of the library and yet not increasing functional diversity significantly.

15　　　　Another approach existing in the art is to design an artificial antibody library computationally and then construct a synthetic antibody library which is expressed in bacteria. Knappik et al., supra. The artificial antibody library was designed based the consensus sequence of each subgroup of the heavy chain and light chain

20　　sequences according to the germline families. The consensus was automatically weighted according to the frequency of usage. The most homologous rearranged sequences for each consensus sequence was identified by searching against the compilation of rearranged sequences, and all positions where the consensus differed from this

25　　nearest rearranged sequence were inspected. Furthermore, models for the seven V_H and seven V_L consensus sequences were built and analyzed according to their structural properties. A library of artificial antibodies were then constructed and expressed in E. coli. This library constructed can be used to screen for antibodies with high affinity

30　　binding to a target molecule.

However, there is a major problem concerning such an approach as far as therapeutic applications of the selected antibody are concerned. Although derived from human sequence pools, the consensus sequences found by using this approach, by definition, are

35　　not natural sequences. (1) Combination of sequences, albeit human

sequences, at various positions may give rise to new immunogenic
epitopes, thus significantly limiting therapeutic applications of the
selected antibodies to human, whereas the method described here can
give either fully human sequences or human derived sequences or both.

5   (2) Consensus sequence has its own serious limitation. Moreover, the
definition of consensus sequence may be too arbitrary and such
artificial sequences defined may not be representative of a natural,
functional structure, although experimental test and structure analysis
may eliminate some unfavorable amino acid combinations. (3)

10   Although the consensus sequences designed to cover mainly those
human germline sequences that are highly used in rearranged human
sequences, it might bias consensus sequence library toward a limited
number of antigens exposed to human being so far, whereas sampling
functional space by mapping structures of different species covers a

15   wide range of functional epitopes of antibodies exposed to a wide array
of antigens. This would be very important for designing antibody
libraries to target novel antigens.

By contrast, the method of the present invention is based on
structural constraints of antibodies directly or derived from natural

20   sources. According to the present invention, a complete structural
repertoire of all antibodies available including both human and other
vertebrates can be analyzed for structural ensembles and/or ensemble
averages within each representative 3D structural family. Based on
this analysis, the structural models are clustered into distinct structure

25   families, each of which includes one or more representative members.
These structure families ideally should represent evenly the structure
space which all antibodies, including those from humans and other
animals, would adopt. Thus, by collecting and building structural
models for each structural ensembles and/or their ensemble averages

30   for these antibodies. a relatively comprehensive survey of functional
repertoire of antibodies across the species may be achieved.

Further, the method of the present invention involves using
selection of native human antibody sequence which fits the best onto
the structural ensemble or ensemble average in each of the structural

35   family. By selecting and pooling the native human sequences based on

- 33 -

the 3D structural templates in each family, a more focused human antibody library is created. The library may be smaller than the native antibody gene pool and yet representative of the functional repertoire of antibody in all vertebrates.

5   Moreover, the sequences of the antibody library constructed using the method of the present invention are closely related to human sequences. The antibody selected from this library against a target molecule should be more desirable than an artificial, non-human antibody for therapeutic applications and humanization of non-human

10   antibodies. This approach can minimize the potential of creating new immunogenic epitopes associated with using synthetic antibody sequences derived from randomization of the consensus sequences.

In addition, the library generated according to the method of the present invention should encompass a broader spectrum of the basic

15   function of an antibody: antigen recognition and neutralization. Since the family of the structural ensemble averages are clustered based on not only the structures adopted by known human sequences, but also structures collected from other vertebrates. In particular, monoclonal antibody produced by mice is a rich source of structures to be included

20   in the process of clustering. Since these monoclonal antibodies are generated from immunization against a vast number of antigens, including these antibodies in the clustering process should tend to enlarge the functional repertoire, although a few special features specific to mice should be taken into account or avoided when applied

25   to human. This approach may effectively avoid the problem associated with known human antibody sequences that are restricted to those isolated against a limited number of antigens.

30   **2.   Process of clustering antibodies based on their structural ensemble or ensemble averages.**

According to the present invention, a master library of human antibody sequence can be constructed based on 3D structural clusters of antibodies from human and other vertebrates. The 3D structural

35   ensembles and/or the ensemble averages serve as master frameworks

upon which human antibody sequences are mapped onto by threading etc and those best compatible are selected to form the master library of human antibody.

The structural ensemble or ensemble averages of antibody from
5   various species may be modeled *in silico* by using various structural alignment methods for comparing antibodies with known 3D structures. By "known 3D structures" is meant x-ray crystal structures, NMR structures, and 3D structures of antibody modeled *in silico*. Currently, there are about 360 antibody 3D structures deposited in the Protein
10 Data Bank (PDB) which include 306 X-ray structures, 17 NMR structures, and 32 modeled structures.

For example, antibody structural cluster can be generated by pairwise structural alignment for V_H or V_L of two or more antibodies with known 3D structures from the PDB. Various algorithms have been
15 developed for protein structure alignment, including those attempting global optimization of the alignment path for some similarity measure using dynamic programming (Orengo et al. (1992) Proteins 14:139-167), Monte Carlo (Holm and Sander (1993) J. Mol. Biol. 233:123-138), 3D clustering (Fischer et al. (1992) J. Biomol. Struct. Dyn. 9: 769-789; and
20 Vriend and Sander (1991) Proteins 11:52-58) and graph theory (Alexandrov (1996) Protein Eng. 9: 727-732), and algorithm using incremental combinatorial extension (CE) of the optimal path (Shindyalov and Bourne (1998) Protein Eng. 9:739-747; and Shindyalov and Bourne (2001) Nucleic Acid Res. 29:228-229).

25 In an embodiment of the present invention, the antibody structural families are clustered by structural alignment using the CE algorithm. Compared to Monte Carlo and 3D clustering algorithms, the CE algorithm significantly reduces the search space and empirically establishes a reasonable target function. The CE target function
30 assumes that alignment path is continuous when including gaps and there is an optimal match between the pair. Various protein properties can also be used with CE algorithm, for example, 1) structure superposition as rigid bodies; 2) inter-residue distance, 3) environmental properties (e.g., exposure, secondary structure); 4)
35 conformational properties (e.g., bond angles, dihedral angles, and

orientation with respect to the protein center of mass).

    As a proof of principle, 3D structures of a series of artificial antibody sequences were compared by using the CE algorithm and classified into a smaller number of clusters based on their 3D

5   structural alignments. These artificial sequences tested are the consensus sequences of the subgroups of the heavy and light chain sequences according to the germline families. Knappik et al., supra. These sequences shown in **Figure 2** consist of the following 7 VH and 7 VL consensus sequences:

10

V_H	V_L
1DHA [SEQ ID NO: 1]	1DGX [SEQ ID NO: 8]
1DHO [SEQ ID NO: 2]	1DH4 [SEQ ID NO: 9]
1DHQ [SEQ ID NO: 3]	1DH5 [SEQ ID NO: 10]
1DHU [SEQ ID NO: 4]	1DH6 [SEQ ID NO: 11]
1DHV [SEQ ID NO: 5]	1DH7 [SEQ ID NO: 12]
1DHW [SEQ ID NO: 6]	1DH8 [SEQ ID NO: 13]
1DHZ [SEQ ID NO: 7]	1DH9 [SEQ ID NO: 14]

15

20

    The seven V_H consensus sequences stored in the PDB, 1DHA, 1DHO, 1DHQ, 1DHU, 1DHV, 1DGW, and 1DHZ, correspond to VH1A, VH1B, VH2, VH3, VH4, and VH6, respectively, as described in Knappik et al., *supra*. The seven V_L consensus sequences stored in the PDB,

25   1DGX, 1DH4, 1DH5, 1DH6, 1DH7, 1DH8, and 1DH9, correspond to VLκ1, VLκ2, VLκ3, VLκ4, VLλ1, VLλ2, and VLλ3, respectively, as described in Knappik et al., *supra*.

    The 3D structural models of these VH and VL consensus sequences built by Knappik et al. were retrieved from the PDB and

30   compared by using the CE algorithm. It should be noticed that CDR3 of the heavy and light chains were the same for all frameworks in the modeled structures. The CE program compares pairs of protein structures of polypeptide chain or their segments based on the root mean square difference (RMSD), their statistical significance (Z-score),

35   length difference, allowable gaps (given as a percentage of the total

number of residues without a matching partner relative to the complete alignment) and sequence identity.

Figure 3 shows the structures of the seven VH sequences superimposed on each other. The structures are aligned by
5   superimposing the Ca atoms using the CE with RMSD < 2Å and Z-score > 4. As shown in Figure 3, the seven VH sequences have a range of conformational variability, especially in the CDR regions. According to Knappik et al., these seven structures cover all canonical classes of the CDRs of the VH structures.

10   However, by using the method of the present invention, a closer look into the seven structures reveals a striking conformational similarity between at least three of the seven VH sequences. By using the CE algorithm, five VH sequences (1DHA, 1DHO, 1DHW, 1DHZ, 1DHV) of the 7 consensus sequences families can be clustered into one
15   structural family with RMSD < 1.5Å and Z-score > 4 and with sequence identity ranging from 48% to 87% using 1dha as standard. Further clustering of the 5 VH sequences (1DHA, 1DHO, 1DHW, 1DHZ, 1DHV) reveals that the 3 VH sequences (1DHA, 1DHO, and 1DHW) collapse into one structural family with RMSD <0.7 Å and Z-score >6 using
20   1DHA as standard, even though their sequence identity ranges widely from 72% to 87% relative to 1DHA.

Figure 4A shows the Ca trace of the superimposed structures of these 3 VH sequences (1DHA in green, 1DHO in cyan, and 1DHW in yellow). Figure 4B shows the superimposed structures with a ribbon
25   representation of the β-sheets of the VH frameworks. As shown in both Figures 4A and 4B, these three structures have an almost perfect superposition (RMSD <0.7 Å) even in the CDR regions. According to the present invention, these three structures are clustered into one VH structure family based on the structural clustering criteria of the
30   present invention. The rest of the 7 VH sequences: 1DHQ, 1DHU, 1DHV, and 1DHZ, have distinctly different structures and thus clustered into 4 distinct structural families with only one member within each family according to the present invention. Thus, by using the method of the present invention, the 7 consensus germlines VH
35   sequences of human antibody designated by Knappik et al. can be

presented by 5 distinctly different structural families. The preferred
criteria are RMSD < 1 Å for each structural family and Z-score > 6.

Figure 5 shows the structures of the seven VL sequences
retrieved from the PDB and superimposed on each other. The
structures are aligned by using 1DGX as the reference structure with
RMSD< 1.6Å and Z-score >6. As shown in Figure 5, the seven VL
sequences have a wide range of conformational variability, especially in
the CDR regions (The structural flexibility at N- and C-termini are
discarded here). According to Knappik et al., these seven structures
cover all canonical classes of the CDRs of the VL structures.

However, by using the method of the present invention, the seven
VL sequences can be re-clustered into smaller number of families. By
using the CE algorithm, four VL sequences (1DGX, 1DH4, 1DH5 and
1DH6) of the 7 consensus sequences families can be clustered into one
structural family with RMSD < 0.6 Å and Z-score >6 and with sequence
identity ranging from 67% to 80% using 1DGX as the structure
reference. Figure 6 shows the superimposed 1DGX(green),1DH4
(yellow), 1DH5 (color cyan) and 1DH6 (magenta) with similar
conformation but varying length in the CDR regions. These four
sequences also belong to the VL kappa sequence family.

Further clustering of the 4 VL sequences (1DGX, 1DH4, 1DH5
and 1DH6) reveals that the 2 VL sequences (1DH4 and 1DH6) collapse
into a structural family with RMSD <0.6 Å and Z-score > 6 with length
of CDR1 loop closer to each other, using 1DGX as the reference, while
two VL sequences (1DGX and 1DH5) can be clustered into another
structural family (data not shown).

Figure 7 shows three superimposed structures of 1DH7, 1DH8,
and 1DH9 in lamda variable light chain, can be clustered into 1
structure family with RMSD < 1.5Å and Z-score > 6 using 1DGX as the
reference according to the present invention.

Thus, by using the method of the present invention, the 7
consensus germlines VL sequences of human antibody designated by
Knappik et al. can be represented by 2 to 3 distinctly different
structural families. Combined with the clustering of the 7 consensus
germlines VH sequences into a 5 structural families, the total structural

family for human antibody germline can be represented by 5 x (2 to 3) =
10 to 15 distinct families, a much reduced structural repertoire than
the germline sequence repertoire of Knappik et al.: 7x7=49.

The structures of the consensus germline VH and VL sequences

5   can also be clustered based on the conformation ensemble adopted by a
specific region of the VH or VL, such as a particular CDR region.

Figure 8A shows that CDR1 regions of the three lamda (λ) VL
sequences (1DH7, 1DH8 and 1DH9) adopt similar conformations with
RMSD < 1Å. Thus, structures of these three lamda VL sequences are

10   clustered into one structural family according to the present invention.

Figure 8B shows that CDR1 regions of the 4 kappa (κ) VL
sequences (1DH4, 1DH6, 1DGX and 1DH5) adopt similar conformations
with RMSD < 0.6Å and gaps of 1-6 amino acids. Thus, structures of
these four kappa VL sequences are clustered into one structural family

15   according to the present invention.

Figure 8C shows that CDR1 regions of the two kappa (κ) VL
sequences (1DH4 and 1DH6) adopt similar conformations with RMSD <
0.6Å and 1 amino acid gap in CDR1. Thus, structures of these two
kappa VL sequences are further clustered into one structural family

20   according to the present invention.

Figure 8D shows that CDR1 regions of the two kappa (κ) VL
sequences (1DGX and 1DH5) adopt similar conformations with RMSD <
0.6Å and 1 amino acid gap in CDR1. Thus, structures of these two
kappa VL sequences are further clustered into one structural family

25   according to the present invention.

As a result of such clustering with a focus on a specific region of
the VH or VL, regions, the number of antibody structure families might
be clustered differently. **Figure 9** shows that clustering of the
structures adopted by the seven consensus germline VL sequences

30   based on the structural families in the CDR1 region led to two to three
distinct families of antibody structures: (1DH7, 1DH8 and 1DH9),
(1DH4 and 1DH6), and/or (1DGX and 1DH5). As shown in **Figure 9**,
within each family, the members adopt similar conformations in its
CDR1 regions with varying length in amino acids.

35   Thus, by further clustering of antibody structures based on a

more focused region of the global structure, i.e., CDR1, the seven
consensus germline VL sequences of human antibody designated by
Knappik et al. can also be represented by 2 to 3 distinctly different
structural families. Combined with the clustering of the 7 consensus

5   germlines VH sequences into 5 structural families, the total structural
families for human antibody framwork sequences can be represented by
5x (2 to 3) = 10 to 15 distinct families, a much more reduced structural
repertoire than the consensus framwork sequence repertoire of Knappik
et al.: 7x7=49.

10   As illustrated by the above example, the method of the present
invention enables one to reduce the size of the antibody sequence
library by clustering them according to their 3D structural families.
Since the structure of a protein or antibody determines its function in
the biological system, the structural ensemble or ensemble average in

15   each structure family of the present invention should represent the
population of diverse antibody sequences sharing similar functions, e.g.
in antigen recognition and affinity binding.

            The above-described method of clustering structures of
consensus human germline antibody sequences only serves as an

20   example to illustrate the principal of the invention. It should be noted
that such a clustering method is not limited to these structures. In a
broader application, structures of both human and non-human
vertebrate antibodies can be combined in a pool and clustered based
their structural ensemble or ensemble averages or representative

25   structure. This approach presumably reduces the risk of the biased
library consisting only of structures of human antibodies generated by
limited exposure to various antigens. By combining and clustering
structures from both human and non-human vertebrate antibodies,
this structural ensemble or ensemble average determined should better

30   represent the functional epitope of the antibody family. In addition,
compared to the approach based on consensus antibody sequences, the
structural ensemble or ensemble average generated by using the
methods of the present invention is based on some well-established
structural principle instead of the ill-defined consensus sequences.

35   The following lists the principles followed in clustering

structures:

a). Align structures based on the RMSD for C alfa carbon atoms in the backbone and Z-score and gaps in the length of amino acids.

b). Clustering structures into the same family progressively based on

5   smaller RMSD values and smaller gaps in amino acids.

c). Clustering structure using globe or important motifs.

It is believed that because structural repertoire is better way to represent functional repertoire, starting from structure should provide

10   an important and more rational basis for library construction. The antibody-antigen interaction occurs on the 3D structure space rather than 1D sequence space. The structure change in CDRs should be better represented in 3D space. Using the structure as the criteria without details into the exact interaction between Ag and Ab should be

15   make it possible to score for human sequence better compatible with the representative structure motif or ensemble.

3.   Selection of Antibody Sequences that Fit onto the Targeted Structural Ensemble or Ensemble Average

20

Once the structures of the antibodies are clustered using methods described above, either the structure ensemble within a cluster or its ensemble average or its representative member can serve as the target structural scaffold in the search for those human antibody

25   sequences that adopt the same or similar 3D structure. For example, an ensemble average of the structures of a target antibody can be used as a structural template in the search in a protein database for antibody sequences with diverse sequences and yet retaining the same functionally relevant structure.

30   In a preferred embodiment, the human antibody sequences are selected from the human immunoglobulin germline sequences. The germline sequences have been clustered into different sequence families including the V-genes, D-genes and J-genes. The rearranged immunoglobin sequences are collected in the Kabat-Wu sequence

35   databases (Johnson & Wu, Kabat Database and its applications: future

directions (2001) 29, 205-206). These human immunoglobin sequences
are retrieved from the Kabat-Wu sequence databases and stored in the
human immunoglobulin (or antibody) sequence data of the present
invention (**Figure 1**).

5   According to the present invention, a variety of methods can be
used to search for those human antibody sequences that adopt the
same or similar structure as the target structural scaffold. The
following are examples of the methods that may be used for achieving
this purpose.

10

      1)   Reverse threading
          The conventional threading of protein sequence is used to predict
the 3D structure scaffold of a protein. Typically, it is a process of
assigning the folding of the protein by threading its sequence to a
15   library of potential structural templates by using a scoring function that
incorporates the sequence as well as the local parameters such as
secondary structure and solvent exposure. Bowie et al. (1991) Science.
253:164-170; Rost et al. (1997) 270:471-480; Xu and Xu (2000)
Proteins: Structure, Function, and Genetics 40:343-354; and
20   Panchenko et al. (2000) J. Mol. Biol. 296:1319-1331. For example, Rost
et al. supra the threading process starts from prediction of the
secondary structure of the amino acid sequence and solvent
accessibility for each residue of the query sequence. The resulting one-
dimensional (1D) profile of the predicted structure is threaded into each
25   member of a library of known 3D structures. The optimal threading for
each sequence-structure pair is obtained using dynamic programming.
The overall best sequence-structure pair constitutes the predicted 3D
structure for the query sequence.

          In contrast, the reverse threading of the present invention is a
30   process of finding the optimal sequence within a library of sequences to
fit onto a target structure. Various scoring functions may be used to
select for the optimal sequence(s) from the library comprising antibody
sequences with various lengths. In a preferred embodiment, the scoring
function is capable of discriminating the following interactions among
35   different sequences with different lengths: (a) The interactions between

the side chains and backbone template as well as between side chains; and (b) the gap penalties for sequences with varying lengths in CDR1, CDR2 and CD3 regions.

For example, amino acid sequences from a human germline immunoglobulin database can be threaded onto the 3D structure of the target structural template (or scaffold) and to search for the sequences with optimal acceptable scores.

2)   Matching the target structure with the optimal sequence composition of multiple aligned sequence family

For this method, the optimal sequence that will fit onto the target structure is selected by matching the target structure with the optimal sequence composition of multiple aligned sequence family. The top hitting sequences found from human antibody sequence database can be optimized at each position with all possible composition to yield the best sequence composition that fits a target structure based on the scoring of the interactions between side chains and backbone and side chain and side chain.

3)   Selecting the optimal sequence by homology alignment with the sequence of the target structure

Another method of selecting human antibody sequence that will fit onto the structural scaffold of each member of the structural family is through homologous alignment with the amino acid sequence of the representative structure within a family. Such a method of structure-based sequence alignment can be practiced by the following procedure.

The target structure may be a member of the structural family clustered by using the method described in Section 1. This target structure serves as a structural scaffold with which a library of human antibody sequences are matched. The matching process is performed through homologous alignment of the library of human antibody sequences with the amino acid sequence of the target structure (the sequence template). This method is a process of indirect structure-based sequence query, instead of directly searching for sequences that can be thread onto the structural scaffold in a reverse threading

process described in Section 1) above. Through homologous alignment
with the sequence template of the target structure, optimal human
antibody sequences will be efficiently selected based on simple sequence
alignment method such as BLAST.

5   The following is an example of selecting optimal human antibody
sequence(s) by using the indirect structure-based sequence alignment
according to the present invention.

This example demonstrates that fully human antibody sequences
with extremely high sequence homology (100% sequence identity) could
10   be found by matching the library of human antibody sequences against
the sequence template of the target structure, i.e., the query sequence.
It can be reasonably assumed that the antibody sequence having the
highest sequence identity with the query sequence should adopt the
same or a very similar structure as that of the query sequence. This
15   sequence(s) is included in the library of selected human antibody to
represent the same scaffold as the target structure. For each member
of the structural family, human antibody sequences can be selected to
match the sequence of the structural ensemble or ensemble average
(there is only one member within each family). The selected human
20   antibody sequences are combined to form a library relatively small in
sequence space and yet functionally diverse.

In this example, the library of human antibody germline
sequences (HuCal sequences) serves as the library of human antibody
sequences (Figure 1). The HuCal sequences in fasta format as shown
25   in Figure 2 were divided into variable light chains and variable heavy
chains. These sequences were then used to compare with human
germline sequences using Blast (Basic Local Alignment Search Tool)

The amino acid sequences of the consensus human germline
sequences that are clustered by using the method described in Section
30   1 serve as the query sequences. Each of the query sequences and the
human germline sequences were aligned and ranked in decreasing
identity. Figure 10 shows the PDB IDs of the query sequence, name of
the retrieved germline gene segment, sequence id no, residues aligned,
high score, P(N) sum, smallest probability, % identity with the query
35   sequence, the germline family to which the identified germline sequence

belongs to (vhaagrp-fl.aa stands for the fl subfamily of VH chain; vkallaa-fl stands for fl subfamily of VL kappa chain; vlallaa-fl.aa stands for fl subfamily of VL lamda chain).

Figure 11 shows the homology alignment for each of the selected

5   human antibody germline sequences with the query sequence.

As shown in Figures 10 and 11, human antibody germline sequences with up to 100% homology with the query sequence can be found from the library of human antibody germline sequences. For example, 1DHA, 1DHW and 1DHV have the identical sequence as the

10   germline sequence segment, while close germiline homologues can be found for other sequences corresponding to the target structural models. These are trivial cases because there is only one query sequence for each structural template.

15   4)   Selecting the optimal remote homologous sequence(s) of structure-based multiple sequence alignment by using profile Hidden Markov Model.

Given one clustered structure family, how to search for optimal

20   sequence(s) that match with their aligned multiple sequence profile corresponding to their structure alignment? The flow chart in Figure 12A illustrates an indirect approach to search for remote homologues consistent with multiple sequence alignment from clustered structures. The clustered structures within a structure family can give multiple

25   sequence alignment based on their 3D structures. These aligned sequences might come from different species; they may be close or remote sequence homologues. The multiple sequence alignment can be used, however, to build a profile Hidden Markov Model (HMM); and this HMM can then be used to select the close and/or remote human

30   homologues from human sequence database such as the human germline and/or rearranged sequence database.

Figure 12B shows the result generated by using the method diagramed in Figure 12A based on a sequence profile of a structure cluster of the FR regions of 3 V_H sequences. The structure cluster of

35   the framework regions of 3 V_H sequences, 1dha, 1dho and 1dhw, is

shown in **Figure 4A**. Sequences of the FR regions of these 3 V_H in the structure cluster were obtained by removing CDR1-3 from V_H, which are designated as FR123 (**Figure 12B**). FR123 sequences were used to build HMM and search human germline antibody sequences or

5   humanized sequences. Fifty-two human germline antibody sequences (i.e., hits for FR123) were found. Variants in each position of the amino acid residues were profiled. Variants that occur less than 5 times in the position were filtered (i.e., cutoff value = 5) and discarded. The rest of the variants were combined combinatorially to produce a library of

10   recombinant FR sequences. The hits for FR123 and/or the recombinant FR sequences can be scored based on their structurally compatibility with the structure cluster of the framework regions.

Figure 12C shows the result generated by using the method diagramed in **Figure 12A** based on a sequence profile of a structure

15   cluster of the CDR1 of 4 kappa V_L sequences. The structure cluster of the 4 kappa V_L sequences, 1dgx, 1dh5, 1dh4, and 1dh6, is shown in **Figure 8B**. Sequences of CDR1 of these 4 kappa V_L sequences in the structure cluster were used to build HMM and search Kabat database. The regions in these 4 kappa V_L sequences showing a greater variability,

20   i.e., the supervariable regions, are highlighted in red (**Figure 12C**). Numerous hits were found with diverse sequences and variable lengths. The hits were grouped according to their lengths. The group having the same length as one of the 4 kappa V_L CDR1 sequences were compared and profiled based on variability in each amino acid residue. Such a

25   variant profile was built for each of the 4 kappa V_L CDR1 sequences, 1dgx, 1dh5, 1dh4, and 1dh6. To demonstrate, hits with lengths different than these 4 target sequences were also selected by using the inventive method, three artificial sequences, 1dh5a, 1dh5b, and 1dh5c, were constructed by inserting more residues into the supervariable

30   region of 1dh5 and used as references to group these hits. As shown in the right portion of **Figure 12C**, hits with lengths different from the 4 "real" target sequences, 1dgx, 1dh5, 1dh4, and 1dh6, were also be found, variant profiles of which were shown underneath each of the 3 artificial sequences.

35   The variant profiles shown in **Figure 12C** reveal that there is a

much higher variability in the supervariable region than the rest of the CDR1. The amino acid residues in the supervariable region may make a greater contribution to the specific and high affinity binding of the antibody to its antigen. This region can be specifically targeted to

5   generate a more focused library of recombinant antibodies for structural and functional screening in silico, in vitro or in vivo.

As also shown in **Figure 12C**, the CDR1 variants with less than 5% of occurrence frequency were filtered and discarded. The rest of the variants were combined combinatorially to produce a library of

10   recombinant CDR1 sequences. The hits for CDR1 and/or the recombinant CDR1 sequences can be scored based on their structurally compatibility with the structure cluster of the 4 kappa V_L CDR1 sequences.

For the reclustered structure family in the Hucal model of

15   Knappik et al., three of the V_H structures are re-clustered into one family based on the structure criteria (superimposition and gaps), these three sequences should be used as the profiled sequences to build their HMM and then search the corresponding human germline sequence that is closest to all of them. **Figure 13 A-C** show the results of the

20   search using this method. The identified human germline sequences (labeled as "Top Hits") can then be used to represent the corresponding structure in our diversity library for the target structures.

As shown in **Figure 13A**, the seven VHs of the Hucal models are clustered into 5 structure families: (1DGA, 1DHO, 1DHW), 1DHQ,

25   1DHU, 1DHV, and 1DHZ. The seven VLs of the Hucal models are clustered into 3 structure families: (1DGX, 1DH5) and (1DH4, 1DH6) for Kappa VL, and (1DH7, 1DH8, 1DH9) for Lamda VL. **Figure 13B** shows the alignment of the amino acid sequences based on the structures of the members within each structure family.

30   **Figure 13 C** lists the top hits of human germline antibodies identified by using the profile HMM method (HMMER2.1.1). The HMM has been calibrated; and E-values are empirical estimates. The top hits to the query sequence profile shows some important features which make it necessary to capture in order to make a comprehensive library

35   for the clustered structure family of 1DHA, 1DHW and 1DHO. It is

- 47 -

noted that 1DHW belongs to a different family of VH (f5 see **Figure 10**) where 1DHA and 1DHO belong to the same family of VH (f1 in **Figure 10**) based on the sequence homology classification. It is also apparent that comparison between hits and query sequence profile show that in

5   some regions the sequence are highly conservative whereas in other regions sequence variability is large. The constant region should be good part for making master framework whereas the highly variable regions are some position for making sequence library.

It should be noted that the order of the top hits depends

10   sensitively on the multiple sequence alignment derived from structure-based alignment. This demonstrates that the structure information is important for selecting the hit sequences. As shown in **Figure 13C**, some of the top hits are nontrivial from those obtained by BLAST.

15   5).   Matching the library of structural template with the library of sequence pools

A powerful approach to compare the target structural template library with the sequence database is to match them in both directions.

20   Using threading to find the optimal template for each sequence among the sequence database and then using reverse threading to match each template structure to sequence in the sequence database. The convergence of the both direction should give a reliable sequence to construct the sequence libraries for the desired target structures. This

25   method can be also used in combination with other sequence searching method such as COBLATH that combines PSI-BLAST with Threading method.

4.   Examples of Structural Computational Engines

30

Many programs are available for modeling structures or structural ensembles of antibodies. For example, a molecular mechanics software may be employed for these purposes, examples of which include, but are not limited to CONGEN, SCWRL, UHBD, and

35   GENPOL.

CONGEN (**CON**formation **GEN**erator) is a program performing
conformational searches on segments of proteins (R. E. Bruccoleri
(1993) *Molecular Simulations* 10, 151-174 (1993); R. E. Bruccoleri, E.
Haber, J. Novotny, (1988) Nature 335, 564-568 (1988); R. Bruccoleri, M.

5   Karplus. (1987) Biopolymers 26, 137-168. It is most suited to problems
where one needs to construct underdetermined loops or segments in a
known structure, i.e. homology modeling. The program is a
modification of CHARMM version 16, and has most of the capabilities of
that version of CHARMM (Brooks BR, Bruccoleri BE, Olafson BD, States

10   DJ, Swaminathan S, Karplus M. (1983) J. Comput. Chem. 4, 187-217).
The energy functions of the total energy include bonds, angles,
torsional angels, improper term, vdw and electrostatic interactions with
distance dependent dielectric constant using Amber94 forcefield in
CONGEN. It provides a simple yet fast way to scan sequence library for

15   their compatibility with their template structure with decent correlation
with the more refined scoring energy functions.

The CONGEN program is a modeling stratagem based on the
theory that the lowest energy conformation should be close or
correspond to the naturally occurring one. Bruccoleri and Karplus

20   (1987) Biopolymers 26:137-168; and Bruccoleri and Novotny (1992)
Immunomethods 96-106. Given an accurate Gibbs function and a
short loop sequence, all of the stereochemically acceptable structures of
the loop can be generated and their energies calculated. The one with
the lower energy is selected.

25   The program can be used to perform both conformational
searches and structural evaluation using standard scoring function.
The program can calculate other properties of the molecules such as
the solvent accessible surface area and conformational entropies, given
steric constraints. Each one of these properties in combination with

30   other properties described below can be used to score the digital
libraries.

The defined canonical structures are available for five of the
CDRs (V_L CDR1, 2, and 3, and V_H CDR1 and 2) except for V_H CDR3. V_H
CDR3 is known to show large variation in its length and conformations,

35   although progress has been made in modeling its conformation with

- 49 -

increasing number of antibody structures becoming available in the PDB (protein data bank) database. CONGEN may be used to generate conformations of a loop region (e.g., V_H CDR3) if no canonical structure is available, to replace the side chains of the template sequence with the

5   corresponding side chain rotamers of the target amino acids. Third, the model will be further optimized by energy minimization or molecular dynamic simulation or other protocols to relieve the steric clash etc in the structure model.

SCWRL is a side chain placing program that can be used to

10   generate side chain rotamers and combinations of rotamers using the backbone dependent rotamer library (Dunbrack RL Jr, Karplus M (1993) J Mol Biol 230:543-574). SCWRL is a program for adding, sidechains to a protein backbone based on the backbone-dependent rotamer library (Bower, MJ, Cohen FE, Dunbrack RL (1997) J Mol Biol

15   267, 1268-1282). The library provides lists of chi1-chi2-chi3-chi4 values and their relative probabilities for residues at given phi-psi values. The program can further explore these conformations to minimize sidechain-backbone clashes and sidechain-sidechain clashes. Once the steric clash is minimized, the side chains and the backbone

20   of the substituted segment can be energy minimized to relieve local strain using CONGEN (Bruccoleri and Karplus (1987) Biopolymers 26:137-168). Each structure is scored using a custom energy function that measures the relative stability of the sequence in the lead structural template.

25   Several automatic programs that are developed specifically for building antibody structures may be used for structural modeling of antibody in the present invention. The ABGEN program is an automated antibody structure generation algorithm for obtaining structural models of antibody fragments. Mandal et al. (1996) Nature

30   Biotech. 14:323-328. ABGEN utilizes a homology based scaffolding technique and includes the use of invariant and strictly conserved residues, structural motifs of known Fab, canonical features of hypervariable loops, torsional constraints for residue replacements and key inter-residue interactions. Specifically, the ABGEN algorithm

35   consists of two principal modules, ABalign and ABbuild. ABalign is the

program that provides the alignment of the antibody V-region sequence whose structure is desired with all the V-region sequences of antibodies whose structures are known and computes scores for the fitting. The highest scoring library sequence is considered to be the best fit to the

5   test sequence. ABbuild then uses this best fit model output by Abalign to generate the three-dimensional structure and provides Cartesian coordinates for the desired antibody sequence.

WAM (Whitelegg NRJ and Rees, AR (2000) Protein Engineering 13, 819-824) is an improved version of ABM which is uses a combined

10   algorithm by (Martin, ACR, Cheetham, JC, and Rees AR (1989) PNAS 86, 9268-9272) Rees etc- to model the CDR conformations using the canonical conformations of CDRs loops from x-ray PDB database and loop conformations generated using CONGEN (see reference by Rees 1995 (Ab antibody engineering). In short, the modular nature of

15   antibody structure make it possible to model its structure using a combination of protein homology modeling and structure predictions.

In a preferred embodiment, the following procedure will be used to model antibody structure. Because antibody is one of the most conserved proteins in both sequence and structure, homology models of

20   antibodies are relatively straightforward, except for certain CDR loops that are not yet determined within existing canonical structures or with insertion or deletions. These loop structures can be, however, modeled using a combined algorithms that combines homology modeling with conformational search (for example, CONGEN can be used for such

25   purpose).

The defined canonical structures for five of the CDRs (L1,2,3 and VH1,2) except for H3 (i.e., V_H CDR3) are used. V_H H3 is known to show large variation in its length and conformations, although progress has been made in modeling its conformation with increasing number of

30   antibody structures become available in the (protein data bank) PDB database using protein structure prediction methods, including threading and comparative modeling, which aligns the sequence of unknown structure with at least one known structure based on the similarity spanning modeled sequence. The de novo or *ab initio*

35   methods also show increasing promising to predict the structure from

sequence alone. The unknown loop conformations can be sampled
using CONGEN if no canonical structure is available (Bruccoleri RE,
Haber E, Novotny J (1988) Nature 355, 564-568). Alternatively, *ab
initio* methods including but not limited to Rosetta ab initio method can
5   be used to predict antibody CDR structures (Bonneau R, Tsai J,
Ruczinski I, Chivian D, Rohl C, Strauss CE, Baker D (2001) Proteins
Suppl 5, 119-126) without relying on similarity at the fold level between
the modeled sequence and any of the known structures. The more
accurate method that uses the state-of-the-art explicit solvent
10   molecular dynamics and implicit solvent free energy calculations can be
used to refine and select for native-like structures from models
generated from either CONGEN or Rossetta *ab initio* method (Lee MR,
Tsai J, Baker D, Kollman PA (2001) J Mol Biol 313, 417-430). The
interactions between CDRs are first scored using the principles that
15   determine the structure of β-sheet barrels in proteins.

5. Scoring functions for evaluating structural compatibility of tester sequence and structural template

20   In the implementation of the inventive methods described above,
thermodynamic computational analysis can be used for evaluating
structural compatibility of a tester sequence with a target structural
template. The structural evaluation is based on an empirical and
parameterized scoring function and is intended to reduce the number of
25   subsequent *in vitro* screenings necessary. The scoring function consists
of three energy terms: nonpolar solvation, sidechain entropy, and
electrostatic energy (Sharp KA. (1998) Proteins 33, 39-48; Novotny J,
Bruccoleri RE, Davis M, Sharp KA (1997) J Mol Biol 268, 401-411).

For energy functions, there are many that can be used to score
30   compatibility of sequences with template structure or structure
ensemble. The scoring function is composed of several terms including
contribution from electrostatic and van der Waals interactions, ΔG_{MM}
calculated using molecular mechanic forcefield, contribution from
solvation including electrostatic solvation and solvent-accessible
35   surface, ΔG_{sol}, and contribution from the conformational entropy.

A simple fast way for computational screening is to calculate structural stability of a sequence using the total or combination of energy terms from molecular mechanic forcefield such as Amber94 implemented in CONGEN.

$$\Delta E_{total} = E_{vdw} + E_{bond} + E_{angel} + E_{electrostatics} + E_{solvation}$$

or alternatively, the binding free energy is calculated as

$$\Delta G_b = \Delta G_{MM} + \Delta G_{sol} (Ag\text{-}Ab) - \Delta G_{sol} (Ag) - \Delta G_{sol} (Ab) - T\Delta S$$

where:

$$\Delta G_{MM} = \Delta G_{ele} + \Delta G_{vdw} \quad (1)$$
$$\Delta G_{sol} = \Delta G_{ele\text{-}sol} + \Delta G_{ASA} \quad (2)$$

The ΔG_{ele} and ΔG_{vdw} electrostatic and van der Waals interaction energy are calculated using Amber94 parameters implemented in CONGEN for ΔG_{MM}, whereas the $\Delta G_{ele\text{-}sol}$ is electrostatic solvation energy required to move a heterogeneously distributed charges from the gas phase into an aqueous phase. This is calculated by solving the Poisson-Boltzmann equation for the electrostatic potential for the reference and mutant structures. ΔG_{ASA}, the nonpolar energy is the energetic cost of moving nonpolar solute groups into polar solvent, resulting in reorganization of the solvent molecules. This has been shown to correlate linearly with the solvent accessible surface area of the molecule (Sitkoff D, Sharp, KA, Honig B (1994) J Phys Chem 98, 1978-1988).

The change in sidechain entropy is a measure of the effect on the local sidechain conformational space particularly at the binding interface. This is calculated from the ratio of the number of allowed sidechain conformations in the reference and mutant structures, in the bound and unbound states. For general scoring purposes, the independent sidechain approximation is applied to the mutated sidechains in order to reduce computational time resulting from sampling the huge conformational space for individual side chains in various structural context.

6.   Energy Functions

Many energy functions can be used to score the compatibility
between sequences and structures. There are four kinds of energy
functions can be used: (1) empirical physical chemistry-based
forcefields based on simple model compounds such as standard
molecular mechanic forcefields discussed below; (2) knowledge-based
statistical forcefields extracted from protein structures, the so called
potential of mean force (PMF) or the threading score derived from the
structure-based sequence profiling (3) parameterized forcefield by
fitting the forcefield parameters using experimental model system; (4)
combinations of one or several terms from (1) to (3) with various'
weighting factor for each term.

The following well-tested physical-chemistry forcefields can be
used or incorporated into the scoring functions. For example, amber 94
fircefield was used in Congen to score the sequence-structure
compatibility in the examples below.   The forcefields include but are
not limited to the following forcefields which are widely used for those
skilled at the art. Amber 94 (Cornell, WD, Cieplak P, Bayly CI, Gould
IR, Merz KM Jr, Ferguson DM, Spellmeyer DC, Fox T, Caldwell JW and
Kollman PA. *JACS* (1995) 117, 5179-5197 (1995); Charmm forcefields
(Brooks, B.R., Bruccoleri, R.E., Olafson, B.D., States, D.J.,
Swaminathan, S., Karplus, M. (1983) J. Comp. Chem. 4, 187-217.;
MacKerell, A D ; Bashford, D; Bellott, M; Dunbrack, R L; Eva seck, J D;
Field, M J; Fischer, S; Gao, J; Guo, H; Ha, S; JosephMcCarthy, D; Kuc
nir, L; Kuczera, K; Lau, F T K; Mattos, C; Michnick, S; Ngo, T; Nguyen,
D T; Pro hom, B; Reiher, W E; Roux, B; Schlenkrich, M; Smith, J C;
Stote, R; Straub, J; W tanabe, M; WiorkiewiczKuczera, J; Yin, D;
Karplus, M (1998) J. Phys. Chem., B 102, 3586-3617).   The Discover
cvff forcefields (Dauber-Osguthorpe, P.; Roberts, V. A.; Osguthorpe, D.
J.; Wolff, J.; Genest, M.; Hagler, A. T. (1988) Proteins: Structure,
Function and Genetics, 4, 31-47.) The ECEPP forcefields (Momany, F.
A., McGuire, R. F., Burgess, A. W., & Scheraga, H. A., (1975) J. Phys.
Chem. 79, 2361-2381.; Nemethy, G., Pottle, M. S., & Scheraga, H. A.,

(1983) J. Phys. Chem. 87, 1883-1887.). The GROMOS forcefields
(Hermans, J., Berendsen, H. J. C., van Gunsteren, W. F., & Postma, J.
P. M., (1984) Biopolymers 23, 1). The MMFF94 forcefields (Halgren, T.
A. (1992) J. Am. Chem. Soc. 114, 7827-7843.; Halgren, T. A. (1996) J.
5   Comp. Chem 17, 490-519.; Halgren, T. A. (1996) J. Comp. Chem. 17,
520-552.; Halgren, T. A. (1996) J. Comp. Chem. 17, 553-586.; Halgren,
T. A., and Nachbar, R. B. (1996) J. Comp. Chem. 17, 587-615.; Halgren,
T. A. (1996) J. Comp. Chem. 17, 616-641.). The OPLS forcefields (see
Jorgensen, W. L., & Tirado-Rives, J.,(1988) J. Am. Chem. Soc. 110,
10   1657-1666.; Damm, W., A. Frontera, J. Tirado-Rives and W. L.
Jorgensen (1997) J. Comp. Chem. 18, 1955-1970.). The Tripose
forcefield (Clark, M., Cramer III, R. D., van Opdenhosch, N., (1989)
Validation of the General Purpose Tripose 5.2 Force Field, J. Comp.
Chem. 10, 982-1012.) . The MM3 forcefield (Lii, J-H., & Allinger, N. L.
15   (1991) J. Comp. Chem. 12, 186-199). Other generic forcefields such as
Dreiding (Mayo SL, Olafson BD, Goddard (1990) J Phy Chem 94, 8897-
8909) or specific forcefield used for protein folding or simulations like
UNRES (United Residue Forcefield; Liwo et al., (1993) Protein Science 2,
1697-1714; Liwo et al., (1993) Protein Science 2, 1715-1731; Liwo et al.,
20   (1997) J. Comp. Chem. 18, 849-873; Liwo et al., (1997) J. Comp. Chem.
18:874-884; Liwo et al., (1998) J. Comp. Chem. 19:259-276.

The statistical forcefields derived from protein structures can be
also used to assess the compatibility between sequences and protein
structure. These potential include but not limited to residue pair
25   potentials (Miyazawa S, Jernigan R (1985) Macromolecules 18, 534-552;
Jernigan RL, Bahar, I (1996) Curr. Opin. Struc. Biol. 6, 195-209). The
potentials of mean force (Hendlich et al., (1990) J. Mol. Biol. 216,
167-180) has been used to calculate the conformational ensembles of
proteins (Sippl M (1990) J Mol Biol. 213, 859-883). However, some
30   limitations of these forcefields are also discussed (Thomas PD, Dill KA
(1996) J Mol Biol 257, 457-469; Ben-Naim A (1997) J Chem Phys 107,
3698-3706). Another methods to score the compatibility between
sequences and structure is to use sequence profiling (Bowie JU, Luthy
R, Eisenberg DA (1991) Science 253, 164-170) or threading scores
35   (Jones DT, Taylor WR, Thornton JM (1992) Nature 358, 86-89; Bryant,

SH, Lawrence, CE (1993) Proteins 16, 92-112; Rost B, Schneider R,
Sander C (1997) J Mol Biol 270, 471-480; Xu Y, Xu D (2000) Proteins
40, 343-354). These statistical forcefields based on the quasichemical
approximation or Boltzmann statistics or Bayes theorem (Simons KT,
5   Kooperberg C, Huang E, Baker D (1997) J Mol Biol 268, 209-225) are
evaluated to assess the goodness of the fit between a sequence and a
structure or for protein design (Dima RI, Banavar J R, Maritan A (2000)
Protein Science 9, 812-819).

     The structure-based thermodynamic or parameters related to
10   formation of the secondary structures of proteins can be also used to
evaluate the fitness between a sequence and a structure. In the
structure-based thermodynamic methods, the thermodynamic ,
quantities such as heat capacity, enthalpy, entropy can be calculated
based on the structure of a protein to explain the temperature-
15   dependence of the thermal unfolding using the thermodynamic data
from model compounds or protein calorimetry studies (Spolar RS,
Livingstone JR, Record MT (1992) Biochemistry 31, 3947-3955; Spolar
RS, Record MT (1994) Science 263, 777-784; Murphy KP, Freire E
(1992) Adv Protein Chem 43, 313-361; Privalov PL, Makhatadze GI
20   (1993) J Mol Biol 232, 660-679; Makhatadze GI, Privalov PL (1993) J
Mol Biol 232, 639-659). The structure-based thermodynamic
parameters can be used to calculate structural stability of mutant
sequences and hydrogen exchange protection factors using ensemble-
based statistical thermodynamic approach (Hilser VJ, Dowdy D, Oas
25   TG, Freire E (1998) PNAS 95, 9903-9908). Thermodynamc parameters
relating to statistical thermodynamic models of the formation of the
protein secondary structures have been also determined using
experimental model systems with excellent agreement between
predictions and experimental data (Rohl CA, Baldwin RL (1998)
30   Methods Enzymol 295, 1-26; Serrano L (2000) Adv Protein Chem 53,
49-85).

     A combination of various terms from molecular mechanic
forcefields plus some specific components has been used in most
protein design programs. In a preferred embodiment, the forcefield is
35   composed of one or several some terms such as the van der Waals,

hydrogen bonding and electrostatic interactions from the standard molecular mechanics forcefields such as Amber, Charmm, OPLS, cvff, ECEPP, plus one or several terms that are believed to control the stability of proteins.

5   **7.   Examples of forcefields for protein design**

It is understood that as a general solution to protein design problem, the energy surface describing the interactions among all elements of the system are sampled as a function of its atomic
10   coordinates over all available sequences and their conformational space. Such a procedure may be implemented in following steps: i) providing a target scaffold with the backbone structure, e.g., a X-ray crystal structure retrieved from protein databank (PDB) or a structural model built by modeling; ii) building side chain models of amino acid variants
15   onto a selected backbone by using a rotamer library derived from a protein structure database; iii) assigning forcefield parameters such as charge, radii, etc. to each atom to construct the target function; and iv) searching the energy surface of the target function using deterministic and/or stochastic algorithms to find optimal solution or solutions
20   ranked in their scores.

Each individual protein design method is distinguished mainly from each other in terms of the forcefield and sampling algorithm. However, scoring functions and sampling algorithms in these protein design methods may optionally be used for a structure-based evaluation
25   of the sequences from the hit and/or hit variant library.

For example, as an important interaction for scoring the correct packing interactions inside the core of proteins, van der Waals (vdw) interaction was used to design the protein core sequences by testing allowed rotamer sequences in enumeration (Ponder JW, Richards FM
30   (1987) J Mol Biol 193, 775-791. A group of sequences can be selected under a potential function using simulated evolution with stochastic algorithm; the ranking order of the energies of selected sequences for residues in the hydrophobic cores of proteins correlates well with their biological activities (Hellinga HW, Richards FM (1994) PNAS 91, 5803-
35   5807).

Similar approaches were also used to design proteins using
stochastic algorithm (Desjarlais J, Handel T, (1995) Protein Science 4,
2006-2018; Kono H, Doi J (1994) Proteins, 19, 244-255). Effect of
potential function on the designed sequences of a target scaffold has
5   been evaluated by including van der Waals, electrostatics, and surface-
dependent semiempirical environmental free energy or combinations of
terms in an automatic protein design method that keeps the
composition of amino acid sequence unchanged. It was shown that
each additional term of the energy function increases progressively the
10   performance of the designed sequences with vdw for packing,
electrostatics for folding specificity and environmental solvation term for
burial of the hydrophobic residues and for exposure of the hydrophilic
residue (Koehl P, Levitt M (1999) J Mol Biol 293, 1161-1181).

The self-consistent mean field approach was used to sample the
15   energy surface in order to find the optimal solution, (Delarue M, Koehl.
(1997) Pac. Symp. Biocomput. 109-121; Koehl P, Delarue M, (1994) J.
Mol. Biol. 239, 249-275; Koehl P, Delarue M (1995) Nat. Struct. Biol.
2,163-170; Koehl P, Delarue M (1996) Curr. Opin. Struct. Biol.
6:222-226; Lee J. (1994) Mol. Biol. 236, 918-939; Vasquez (1995)
20   Biopolymers 36, 53-70). Combination of terms from Molecular
Mechanics or MM forcefield, knowledge-based statistical forcefield and
other empirical correction has been also used to design protein
sequences that are close to the native sequence of the target scaffold
(Kuhlman B, Baker D (2000) PNAS 97, 10383-10388). The structure-
25   based thermodynamic terms were included in addition to the steric
repulsion in the protein core design (Jiang X, Farid H, Pistor E, Farid
RS (2000) Protein Science 9, 403-416). Knowledge-based potentials
have been used to design proteins (Rossi A, Micheletti C, Seno F,
Maritan A (2001) Biophysical Journal 80, 480-490).

30   Forcefields have been also optimized specifically for protein
design purpose. The energy function is decomposed into pairwise
functional forms that combine molecular mechanic energy terms with
specific solvation term is used for residues at the core, boundary and
surface positions; dead end elimination algorithm is used to sip through
35   huge number of combinatorial rotameric sequences (Dahiyat BI, Mayo

SL (1996) Protein Science 5, 895-903). The stringency of force fields,
and rigid inverse folding protocol with fix backbone used in protein
design has inevitably resulted a significant rate of false negative:
rejection of many sequences that might be acceptable if soft energy
5   function or flexible backbone is allowed. Moreover, the energy function
used for protein design is so different from forcefields such as Amber or
Charmm that are widely used and tested for studying protein folding or
stability (Gordon DB, Marshall SA, Mayo SL (1999) Curr Opion Stru Biol
9, 509-513). Cautions should be excised to compare the sequences
10   designed using specific protocol with others from alternative methods
because a direct comparison among them may not be possible due to
the false negative issues involved in protein design protocols.

The inventor believes that although a high false negative rate in
protein design is not a problem for designing proteins with no
15   restriction, this will pose serious problem for designing proteins for
pharmaceutical application because only small restrictive region is
allowed to have altered sequences to improve protein functions such as
the CDRs in antibodies and a few positions in the framework regions.
Therefore, it is accuracy rather than the speed of computational
20   screening that matters the most for functional improvement in order to
identify those few mutants in the targeted region.

These methods can be used to generate structure ensembles by
molecular dynamics calculations or computational methods of proteins
in the native or unfolded states which provide more accurate methods
25   to score sequence and its variants based on the ensemble averages of
the energy functions (Kollman PA, Massova I, Reyes C, Kuhn B, Huo
SH, Chong LT, Lee M, Lee TS, Duan Y, Wang W, Donini O, Cieplak P,
Srinivasan P, Case DA, and Cheatham TE (2000) Acc. Chem Res. 33,
889-897). The ensemble averages calculated from ensemble structures
30   show better correlation with corresponding data from experimental
measurement.

In a particular embodiment, standard terms from MM terms have
been combined with the solvation terms including electrostatic solvation
and solvent-accessible solvation term calculated with continuous
35   solvent model for electrostatic solvation; these MM-PBSA or MM-GBSA

method, together with contribution from the conformational entropy including backbone and side chains, have shown good correlation between experimental and calculated values in the free energy change (Wang W, Kollman P (2001) JMB). Compared to other scoring functions

5   used in protein and drug design, MM-PBSA or MM-GBSA is better physical model for scoring and would handle various problems on an uniform basis, although it is computational expensive because multiple trajectories from molecular dynamic simulation in explicit water is required to calculate the ensemble averages for the system.

10

CLAIMS

What is claimed is:

5   1.   A method for constructing a library of recombinant antibodies,
comprising the steps of:

clustering variable regions of a collection of antibodies having
known 3D structures into at least two families of structural ensembles,
each family of structural ensemble comprising at least two different
10   antibody sequences but with substantially identical main chain
conformations;

selecting a representative structural template from each family of
structural ensemble;

profiling a tester polypeptide sequence onto the representative
15   structural template within each family of structural ensemble; and

selecting the tester antibody sequence that is compatible to the
structural constraints of the representative structural template.

2.   The method of claim 1, wherein the collection of antibodies
20   include antibodies or immunoglobulins collected in a protein database.

3.   The method of claim 2, wherein the protein database is selected
from the group consisting of the protein data bank of Brookhaven
National Laboratory, genbank at the National Institute of Health, and
25   Swiss-PROT protein sequence database.

4.   The method of claim 1, wherein the collection of antibodies
having known 3D structures include antibodies having resolved X-ray
crystal structures, NMR structures or 3D structures based on
30   structural modeling.

5.   The method of claim 1, wherein the variable regions of the
collection of antibodies are the full length heavy chain or light chain
variable regions or specific portions of the heavy chain or light chain

variable region selected from the group consisting of CDR, FR, and a combination thereof.

6.   The method of claim 5, wherein the CDR is CDR1, CDR2, or
5   CDR3 of an antibody.

7.   The method of claim 5, wherein the FR is FR1, FR2, FR3, or FR4 of an antibody.

10   8.   The method of claim 1, wherein the clustering step includes clustering the collection of antibodies such that the root mean square difference of the main chain conformations of antibody sequences in each family of the structural ensemble is less than 4 Å.

15   9.   The method of claim 1, wherein the clustering step includes clustering the collection of antibodies such that the root mean square difference of the main chain conformations of antibody sequences in each family of the structural ensemble is less than 3 Å.

20   10.   The method of claim 1, wherein the clustering step includes clustering the collection of antibodies such that the root mean square difference of the main chain conformations of antibody sequences in each family of the structural ensemble is less than 2 Å.

25   11.   The method of claim 1, wherein the clustering step includes clustering the collection of antibodies such that the root mean square difference of the main chain conformations of antibody sequences in each family of the structural ensemble is between about 0.1-4.0 Å.

30   12.   The method of claim 1, wherein the clustering step includes clustering the collection of antibodies such that the Z-score of the main chain conformations of antibody sequences in each family of the structural ensemble is more than 2.

13.   The method of claim 1, wherein the clustering step includes
clustering the collection of antibodies such that the Z-score of the main
chain conformations of antibody sequences in each family of the
structural ensemble is more than 3.

5

14.   The method of claim 1, wherein the clustering step includes
clustering the collection of antibodies such that the Z-score of the main
chain conformations of antibody sequences in each family of the
structural ensemble is more than 4.

10

15.   The method of claim 1, wherein the clustering step includes
clustering the collection of antibodies such that the Z-score of the main
chain conformations of antibody sequences in each family of the
structural ensemble is between about 2-8.

15

16.   The method of claim 1, wherein the clustering step is
implemented by an algorithm selected from the group consisting of CE,
Monte Carlo and 3D clustering algorithms.

20   17.   The method of claim 1, wherein the profiling step includes
reverse threading the tester polypeptide sequence onto the
representative structural template within each family of structural
ensemble.

25   18.   The method of claim 1, wherein the profiling step is implemented
by a multiple sequence alignment algorithm.

19.   The method of claim 18, wherein the multiple sequence
alignment algorithm is profile HMM algorithm or PSI-BLAST.

30

20.   The method of claim 1, wherein the representative structural
template is adopted by a CDR region, and the profiling step includes
profiling the tester polypeptide sequence that is a variable region of a
human or non-human antibody onto the representative structural
35   template within each family of structural ensemble.

21. The method of claim 1, wherein the representative structural template is adopted by a FR region, and the profiling step includes profiling the tester polypeptide sequence that is a variable region of a

5   human antibody onto the representative structural template within each family of structural ensemble.

22. The method of claim 21, wherein the tester polypeptide sequence is a variable region of human germline antibody sequence.

10

23. The method of claim 1, wherein the tester polypeptide sequence is the sequence or a segment sequence of an expressed protein.

24. The method of claim 1, wherein the tester polypeptide sequence

15   is a region of an antibody.

25. The method of claim 24, wherein the antibody is a human antibody.

20   26. The method of claim 1, wherein the tester polypeptide sequence is a region of a human germline antibody sequence.

27. The method of claim 1, wherein the selecting step includes selecting the tester polypeptide sequence by using an energy scoring

25   function selected from the group consisting of electrostatic interactions, van der Waals interactions, electrostatic solvation energy, solvent-accessible surface solvation energy, and conformational entropy.

28. The method of claim 1, wherein the selecting step includes

30   selecting the tester polypeptide sequence by using a scoring function incorporating a forcefield selected from the group consisting of the Amber forcefield, Charmm forcefield, the Discover cvff forcefields, the ECEPP forcefields, the GROMOS forcefields, the OPLS forcefields, the MMFF94 forcefield, the Tripose forcefield, the MM3 forcefield, the

35   Dreiding forcefield, and UNRES forcefield, and other knowledge-based

statistical forcefield (mean field) and structure-based thermodynamic potential functions.

29.   The method of claim 1, further comprising the steps of:
        building an amino acid positional variant profile of the selected tester polypeptide sequences;
        filtering out the variants with occurrence frequency lower than 3; and
        combining the variants remained to produce a combinatorial library of antibody sequences.

30.   The method of claim 29, wherein the filtering step includes filtering out the variants with occurrence frequency lower than 5.

31.   The method of claim 1, further comprising the following:
        introducing the DNA segment encoding the selected tester polypeptide into cells of a host organism;
        expressing the DNA segment in the host cells such that a recombinant antibody containing the selected polypeptide sequence is produced in the cells of the host organism; and
        selecting the recombinant antibody that binds to a target antigen with affinity higher than 10^6 M^{-1}.

32.   The method of claim 31, wherein the recombinant antibody is a fully assembled antibody, a Fab fragment, an Fv fragment, or a single chain antibody.

33.   The method of claim 31, wherein the host organism is selected from the group consisting of bacteria, yeast, plant, insect, and mammal.

34.   The method of claim 31, wherein the target antigen is a small molecule, proteins, peptide, nucleic acid or polycarbohydate.

35.   A method of constructing a library of recombinant antibodies based on

a target structural template, comprising the steps of:

      providing a target structural template of a variable region of one or more antibodies;

      profiling a tester polypeptide sequence onto the target structural

5   template; and

      selecting the tester polypeptide sequence that is structurally compatible with the target structural template.

36.   The method of claim 35, wherein the target structural template is

10   a 3D structure of a heavy chain or light chain variable region of an antibody.

37.   The method of claim 36, wherein the heavy chain or light chain variable region of an antibody is a CDR, a FR or a combination thereof.

15

38.   The method of claim 35, wherein the target structural template is a 3D structural ensemble of heavy chain or light chain variable regions of at least two different antibodies.

20   39.   The method of claim 38, wherein the heavy chain or light chain variable regions are CDRs, FRs or combinations thereof.

40.   The method of claim 35, wherein the profiling step includes reverse threading the tester polypeptide sequence onto the target

25   structural template.

41.   The method of claim 35, wherein the profiling step is implemented by a multiple sequence alignment algorithm.

30   42.   The method of claim 41, wherein the multiple sequence alignment algorithm is profile HMM algorithm or PSI-BLAST.

43.   The method of claim 35, wherein the target structural template is adopted by a CDR region, and the profiling step includes profiling the

35   tester polypeptide sequence that is a variable region of a human or non-

human antibody onto the representative structural template within each family of structural ensemble.

44.   The method of claim 35, wherein the target structural template is adopted by a FR region, and the profiling step includes profiling the tester polypeptide sequence that is a variable region of a human antibody onto the representative structural template within each family of structural ensemble.

45.   The method of claim 44, wherein the tester polypeptide sequence is a variable region of human germline antibody sequence.

46.   The method of claim 35, wherein the tester polypeptide sequence is the sequence or a segment sequence of an expressed protein.

47.   The method of claim 35, wherein the tester polypeptide sequence is a region of an antibody.

48.   The method of claim 35, wherein the antibody is a human antibody.

49.   The method of claim 35, wherein the tester polypeptide sequence is a region of a human germline antibody sequence.

50.   The method of claim 35, wherein the selecting step includes selecting the tester polypeptide sequence by using an energy scoring function selected from the group consisting of electrostatic interactions, van der Waals interactions, electrostatic solvation energy, solvent-accessible surface solvation energy, and conformational entropy.

51.   The method of claim 35, wherein the selecting step includes selecting the tester polypeptide sequence by using a scoring function incorporating a forcefield selected from the group consisting of the Amber forcefield, Charmm forcefield, the Discover cvff forcefields, the ECEPP forcefields, the GROMOS forcefields, the OPLS forcefields, the

MMFF94 forcefield, the Tripose forcefield, the MM3 forcefield, the
Dreiding forcefield, and UNRES forcefield, and other knowledge-based
statistical forcefield (mean field) and structure-based thermodynamic
potential functions.

.5

52.   The method of claim 35, further comprising the steps of:
            building an amino acid positional variant profile of the selected
tester polypeptide sequences;
            filtering out the variants with occurrence frequency lower than 3;
10   and
            combining the variants remained to produce a combinatorial
library of antibody sequences.

53.   The method of claim 52, wherein the filtering step includes
15   filtering out the variants with occurrence frequency lower than 5.

54.   The method of claim 35, further comprising the following:
            introducing the DNA segment encoding the selected tester
polypeptide into cells of a host organism;
20   expressing the DNA segment in the host cells such that a
recombinant antibody containing the selected polypeptide sequence is
produced in the cells of the host organism; and
            selecting the recombinant antibody that binds to a target antigen
with affinity higher than 10^6 M^{-1}.

25

55.   The method of claim 54, wherein the recombinant antibody is a
fully assembled antibody, a Fab fragment, an Fv fragment, or a single
chain antibody.

30   56.   The method of claim 54, wherein the host organism is selected
from the group consisting of bacteria, yeast, plant, insect, and mammal.

57.   The method of claim 54, wherein the target antigen is a small
molecule, proteins, peptide, nucleic acid or polycarbohydate.

35

58.   A method for constructing a library of recombinant antibodies,
comprising the steps of:

        providing a target sequence of a heavy chain or light chain
variable region of a target antibody;

5   aligning the target sequence with a tester polypeptide sequence;
and

        selecting the tester polypeptide sequence that has at least 15%
sequence homology with the target sequence.

10   59.   The method of claim 58, wherein the target sequence is the full
length heavy chain or light chain variable region of the target antibody
or specific portions of the variable regions of the target antibody
selected from the group consisting of CDR, FR, and a combination
thereof.

15

60.   The method of claim 59, wherein the CDR is CDR1, CDR2, or
CDR3 of the target antibody.

61.   The method of claim 59, wherein the FR is FR1, FR2, FR3, or
20   FR4 of the target antibody.

62.   The method of claim 58, wherein the aligning step includes
aligning the target sequence with the polypeptide segment of the tester
polypeptide sequence by using a sequence alignment algorithm.

25

63.   The method of claim 62, wherein the sequence alignment
algorithm is
selected from the group consisting of BLAST, PSI-BLAST, profile HMM,
and COBLATH.

30

64.   The method of claim 58, wherein the target sequence is a CDR
region of the target antibody, and the alignment step includes aligning
the tester polypeptide sequence that is the sequence or segment
sequence of an expressed protein with the target sequence.

35

65.   The method of claim 58, wherein the target sequence is a FR
region of the target antibody, and the alignment step includes aligning
the tester polypeptide sequence that is the sequence or segment
sequence of a human antibody protein with the target sequence.

5

66.   The method of claim 58, wherein the selecting step includes
selecting the tester polypeptide sequence that has at least 25%
sequence homology with the target sequence.

10   67.   The method of claim 58, wherein the selecting step includes
selecting the tester polypeptide sequence that has at least 35%
sequence homology with the target sequence.

68.   The method of claim 58, wherein the selecting step includes
15   selecting the tester polypeptide sequence that has at least 35%
sequence homology with the target sequence.

69.   The method of claim 58, further comprising the steps of:
        building an amino acid positional variant profile of the selected
20   tester polypeptide sequences;
        filtering out the variants with occurrence frequency lower than 3;
and
        combining the variants remained to produce a combinatorial
library of antibody sequences.

25

70.   The method of claim 58, wherein the filtering step includes
filtering out the variants with occurrence frequency lower than 5.

71.   The method of claim 58, further comprising the following:
30   introducing the DNA segment encoding the selected tester
polypeptide into cells of a host organism;
        expressing the DNA segment in the host cells such that a
recombinant antibody containing the selected polypeptide sequence is
produced in the cells of the host organism; and

selecting the recombinant antibody that binds to a target antigen with affinity higher than 10^6 M^{-1}.

72.   The method of claim 51, wherein the recombinant antibody is a

5   fully assembled antibody, a Fab fragment, an Fv fragment, or a single chain antibody.

10

Structure-based construction of human antibody library

Database of antibody structures and models in PDB etc
Database of human germline and rearranged Ig sequences

Clustering structures into structure families by structure alignment, gaps etc using the global structure or specific motifs such as CDRs

direct selection

1. Select sequence(s) fitting onto the target structure template from germline and rearranged sequence database using by reverse threading etc
2. Select the master framework sequences for each distinct structure family from the top hits
3. Pool the sequences and their combinatorial combinations at certain cut off for CDRs

Dual selection

1. Select sequence(s) from germline and rearranged sequence database using dual selection such as coblath and double threading for each structure template
2. Select the master framework sequences for each distinct structure family using convergent top hits
3. Pool the sequences and their combinatorial combinations at certain cut off for CDRs

Indirect selection

1. Select sequence(s) from germline and rearranged sequence database using the sequence or sequence profile of each structure family
2. Select the master framework sequences for each distinct structure family using top hits given by the query sequence and sequence profile
3. Pool the sequences and their combinatorial combinations at certain cut off for CDRs

- Select the master frameworks for both VH and VL.
- Combine the selected framework with designed CDR libraires
- Synthesize the human antibody library

FIGURE 13C

Top Hits of Human Germline Antibody Sequences that Adopt the Target Structure or Scaffold of the reclustered Hucal family by Using the Profile HMM Method

1) For the clustered structure family for 1DHA, 1DHO and 1DHW of VH, the top hits are listed below:

The sequences(1DHA:H, 1DHO:H and 1DHW:H) used to build the HMM are aligned with its top hits from germline sequences using HMMER 2.1.1

Sequence	Description	Score	E-value	N
DP-73/V5-51...+		232.9	4.5e-68	1'
VHVCW/COS-24+		232.9	4.5e-68	1
DP-88/hv1051K...+		232.1	8.1e-68	1
DP-10/hv1051...+		231.4	1.3e-67	1
2M27/11M27...		231.4	1.3e-67	1
VHGL1.8		231.4	1.3e-67	1
VHVJB		229.8	3.9e-67	1
VHGL1.2		229.8	3.9e-67	1
RR.VH1.2		229.4	5e-67	1
6M27		229.3	5.6e-67	1
VH251Shen+		229.1	6.2e-67	1
DP-75/VI-2...+		229.0	6.8e-67	1

The top hits to the profile HMM are aligned to the original structure-based sequence alignment are shown below.

INTERNATIONAL SEARCH REPORT

A. CLASSIFICATION OF SUBJECT MATTER	
IPC(7) : G01N 31/00; G06F 19/00	
US CL : 702/27	

According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)
U.S. : 702/27

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practicable, search terms used)
Please See Continuation Sheet

C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category *	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
X	KNAPPIK et al. Fully Synthetic Human Combinatorial Antibody Libraries (HuCAL) Based on Modular Consensus Frameworks and CDRs Randomized with Trinucleotides, Journal of Molecular Biology. Issued 11 February 2000, Volume 296, pages 57-86, see entire document.	1-72
X — Y	IBA et al. Changes in the specificity of antibodies against steroid antigens by introduction of mutations into complementarity-determining regions of the VH domain. Protein Engineering. Issued May 1998, Volume 11, Number 5, pages 361-370, see entire document.	1-6, 35-39, and 58-60 ————— 7-34, 40-55, and 61-72
Y	CHOTHIA et al. Structural Determinants in the Sequences of Immunoglobulin Variable Domain. Journal of Molecular Biology. Issued 1 May 1998, Volume 278, pages 457-479, see entire document.	1-72

☐ Further documents are listed in the continuation of Box C.	☐ See patent family annex.

* Special categories of cited documents:	"T" later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention
"A" document defining the general state of the art which is not considered to be of particular relevance	
"E" earlier application or patent published on or after the international filing date	"X" document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone
"L" document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)	"Y" document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art
"O" document referring to an oral disclosure, use, exhibition or other means	
"P" document published prior to the international filing date but later than the priority date claimed	"&" document member of the same patent family

Date of the actual completion of the international search	Date of mailing of the international search report
26 July 2002 (26.07.2002)	27 AUG 2002
Name and mailing address of the ISA/US	Authorized officer
Commissioner of Patents and Trademarks Box PCT Washington, D.C. 20231	Channing S. Mahatan
Facsimile No. (703)305-3230	Telephone No. (703) 308-0196

Form PCT/ISA/210 (second sheet) (July 1998)
